To create attractive and correctly-planned surroundings does not mean that the decorator must resort to a monumental scale in the decoration, which is solely architectural, and pertains to the proportions and the formal decorative treatment associated with marble or inlaid polished wood floors, elaborately treated walls and ceilings in the interiors of great houses and palaces. The basic principles of good design are the same, however, whether used in formal decoration, monumental in scale, or informal, simple schemes of decoration. It is only in their application that they differ.

The decorative treatment of any interior is, after all, an expression of the personality of its owner, and it should form a suitable background for the family's everyday way of living. But since there is great diversity of individuals and their tastes, there can be no fixed rules nor can beauty be confined to any particular style. The result in every case expresses more or less complexity of motive, and upon this largely depends the charm of the room if its reason for existing is to be coherent. The two things above all others needed to secure coherence and clearness of expression are: good composition in furniture arrangement (the result of good planning) and expert disposal of the color scheme and of the accessories.

Selecting a Decorative Theme.—Once the family's pattern of living is established, the next step in order to create a proper background is for the decorator to decide upon the decorative theme as a means of conferring personality and helping in creating the proper atmosphere. Deciding upon the decorative theme will depend upon whether Early American and a Cape Cod type of house is desired, for example, or whether the preference is toward ornate Chippendale and a Georgian house, vigorous Sheraton and a Regency house, or the contemporary style and a modern house.

For no interior can be slap-dash in its decorative treatment and be satisfactory. It demands careful consideration of architectural background, furnishings and accessories. Just as every successfully planned and decorated room must have a focal center—a radiating center of interest for its entire scheme—so does it depend upon its accessories to distribute this interest, in turn, about the room. It is through the dissemination of a single idea, or theme, in its decoration that the successful room differs from the poorly decorated one and reveals itself as an organic entity.

Once a theme of decoration is established, the next step is to consider the functions of the respective rooms and to allot each a share in the estimate of costs, depending upon its relative importance in the family's pattern of living.

The proper approach to any scheme of decoration is a resolve to develop rooms of individuality without recourse to any others of similar type. If this precept is observed, interiors will result in neither a traditional style nor the transient vogues of the present.

Begin with a Plan.—Planning is the first step to successful decoration. And organization is the method by which the plan is brought to completion. One patterns the plan around the living habits of the family. If the plan is a good one, there will be no continuous redecorating and moving furniture about, only an occasional re-furbishing. Any object which does not fit into the plan, no matter how much it may be esteemed for sentimental reasons, should be ruthlessly discarded.

With the planning the decorator includes a preliminary investigation of any existing decoration, considers any favorable architectural elements, and, even before making an estimate of costs, ascertains what new furniture, draperies, wall covering, and rugs are needed. Architectural

changes, if any, are carefully studied and door and window openings, as well as old lighting fixtures and woodwork, considered for possible re-

placement. An estimate of costs would also include any new furnishings, repainting and re-finishing and reupholstering of furniture not discarded. And new floor coverings, draperies and bedding will contribute much toward making any old bedroom assume an attractive appearance.

Backgrounds.—Walls have to be ornamented if they are to assume their chief purpose as a decorative background, and usually they form the basis for an entire scheme. Color and texture

papers (see WALL COVERINGS) will always remain deserved favorites because they are often-times peculiarly appropriate in small interiors to give an effect of increased space, or to supply stimulating decorative interest in incidental rooms such as guestroom, dining room, or bathroom. Iconoclastic practice pervades the modern use of patterned wall coverings, and the old rule of small rooms requiring small designs, because the reiteration of pattern is less conspicuous, no

A formal living room in contemporary style acquires a sophisticated air by contrasting sharp color in few furnishings against an off-white background. Furniture was designed by David Wider.

are all that are required to give walls life and interest, but pattern will be needed to contribute additional character.

Because of the importance that walls assume in decoration, they have to be treated as background for the furnishings or as pure decoration in themselves. The competent decorator is never at a loss in combining these two essential factors, if necessary, to produce flawless rooms indicative of the owner's taste and interests; he carefully weighs the degree of ornament and color value in walls against the respective decoration in the other surfaces and produces a total effect that is decorative yet never insistent.

A poorly proportioned lamp, an awkward bowl, or similar accessories that are wrong in color can be ignored, but the things that go on the wall—that are part of the background—are hard to overlook if they are shriekingly bad. And it is better to have none at all than to have these. There is great diversity in the accessories that belong on the wall: ranging from fine floral panels to individual pictures, and including fabrics, any of which can be counted upon to add pattern as well as color; and there are paintings on canvas, wood, or glass.

Patterned backgrounds in the guise of wall-

paper holds; for, surprisingly, a giant pattern is frequently the only refuge in certain situations such as a long narrow hall studded with door openings and containing no furniture.

Decorative wall coverings—paint, wallpaper, grasscloth, etc.—are generally used either to coalesce the color schemes of the various rooms into a harmonious whole with one room opening naturally into another, or to permit greater variety in the individual color scheme of each room.

The decorator is motivated in a choice of backgrounds by two considerations: Is the room to be pretentious in scheme or simple? Is it to be stimulating or reposeful in character? Regardless of the decorative treatment, another consideration is suitability in purpose, color, pattern, and scale. A factor in selecting a wall covering is whether it will blend with the woodwork, furniture, and draperies once it is on the wall. Designs that obtrude into the room or indicate any movement in pattern should be ignored.

Wall treatments can best be determined by one or the other of two methods: derive the color scheme from the colors in the design of the wall covering itself; or decide first upon the color scheme and fit the wall covering to it.

Another determining factor in any considera-

tion of the decorative background is the floor. In addition to wood, of which there are several different types, including patterned parquetry, or parquet, the more popular floorings include linoleum, stone, brick, rubber, cork, asphalt, tile, and those made of vinyl products. A floor of any one of these materials can be developed in a design appropriate to any scheme, either as a dominant decorative element or as a background for the rug.

A wall-to-wall carpet, or room-size rug, will make a small room appear larger; and it will also help to unify an irregularly shaped room. Or an area rug can be used as an island for the main grouping of seating furniture in the room, and the rest of the floor left bare, waxed, and polished. For the inexpensive house, there is the woven fiber rug in various textures, weaves, and patterns. For the formal living room or dining room, a shiny vinyl, rubber, or linoleum tile floor with inlaid design of brass strips is recommended.

Contrast is usually the key that makes decorative schemes interesting, whether it is in a mixture of light, medium and dark colors, the hard and soft textures of fabrics, round and oblong shapes of furniture, or high and low eye-levels of accessories and draperies. The factor of contrast is particularly important in developing color harmony.

Color Harmony.—If furniture is the contributing factor of character in an interior, then color, more than anything else, gives a room its personality. And of all the manifold problems of decoration there is none so vital, nor one which evidences so surely a comprehension of the subject, as a deft handling of color.

Yet the correct use of color in decoration can be quite simple, although the very success of every

interior depends upon it, regardless of the style and quality of furnishings used. Indeed with color alone a room may have its architectural features emphasized, or minimized; it can be made to appear larger or smaller, higher or lower; it can be made brighter or darker, warmer or cooler.

A room without window walls and a view need not stress the lack by an atmosphere of confinement. With a flowering print of linen or cotton used with a free hand throughout a room, an effect of a garden can be suggested that will contribute such freshness and beauty that the view will not be missed.

An interesting color treatment can be realized by selecting favorite colors—blue, yellow-green, and lavender, for example—and tying them together with chalk white. White, in this instance, unifies the color scheme, and, like the use of a little black, gives the scheme balance.

Two other new color schemes, featuring brilliant colors against a monochromatic background, include electric blue and silver fabrics, combined with bone-white walls and dark furniture; or a brilliant pink or turquoise background accented with black and white.

Still another novel idea would be to paint the ceiling a strong bright color and, by means of reflected light, tone the entire room.

The development of any color scheme is predicated upon an acquaintance with the vivid *primary* colors, red, blue and yellow; the *secondary* colors, green (yellow mixed with blue), orange (yellow mixed with red), and purple (blue mixed with red); the *complementary*, or contrasting, colors including red with green, yellow with purple, and blue with orange; and the variable *tints* (produced by the addition of white) and *shades* (produced by the addition of black). A tertiary color,

of which there are six, is the combination of a secondary color with a primary color. A *muted* color is obtained by mixing both black and white to any color, tint or shade.

The simplest way to develop a color scheme is to select a color in the rug or curtain fabric (if patterned) and assemble other colors in the room around it. The color selected will be the *basic* color. Used in such manner, either a *harmonious*

or a *contrasting* scheme will result, depending upon the colors assembled with the basic color. The colors in a room keyed to a single hue, such as crimson with rose and pink, results in a *monochromatic* color scheme. A *related* color scheme results from combining a single hue with related colors, as red with purple and blue, or purple with lilac and blue. For effectiveness, the number of major colors in a scheme should be limited to two or three, so that their *contrast* value is emphasized, and the effect can be spiced by the addition of a small quantity of related color. These *accenting* colors, either contrasting or harmonizing, are necessary in preventing the scheme from being flat and uninteresting. Too many accenting colors, however, may cause confusion in the decorative scheme.

Color should never overwhelm. A background color should be restful enough for leisure, yet stimulating enough for work. Unity can be achieved without monotony by varying the tones and textures of the furnishings which reflect light in different ways. Light, bright colors such as pink and yellow, or green and blue, suggest a gay, friendly atmosphere.

Formerly the cool colors, such as blue and gray, were not recommended for rooms with a northern exposure; a better selection being the warm colors, such as red or orange. Nor were

An "outdoor" atmosphere is given a living-dining room decorated by Elizabeth Banning, A.I.D. Furniture includes dining table used for games and a corner grouping for conversation and television.

warm colors used in rooms with a southern exposure; here a better selection being the cool colors. But air conditioning has made the interior decorator independent in his choice, so that colors now are used as desired with no consideration of room exposure.

Cool colors have the effect of increasing the size of a room, just as warm colors tend to diminish it. Similarly, dark colors tend to make rooms appear small and crowded, and light colors give them an atmosphere of spaciousness. Nevertheless beautiful rooms of rather formal aspect can be planned around black, white, and gray when either used alone or combined with other colors. Walls and woodwork painted the same color tend to make rooms seem larger. An effect of increased spaciousness can also be obtained by painting connecting rooms the same color, so that they appear to flow together. And too-high ceilings can be made to appear lower by being painted a darker color than the walls. A too-wide room can be made to seem narrower by painting the side walls darker than the end walls; and the room can be made to appear wider by reversing the process.

Background colors should be definite and fresh, in such clear light hues as lilac, pink, saffron, yellow, blue, and green, never of an indeterminate dark hue. The ceiling should be included in the background, and may be the same

color as the walls, or painted a contrasting color, preferably the same light or dark value. If the floor is wood, it should be stained dark walnut—never left in a light finish lest it not stay "down"—then waxed and polished.

Improper illumination can "spoil" any color scheme at night, regardless of how attractive it may be in daylight, therefore time spent in planning adequate lighting—including the distribution of lamps in the room for the best effect—will prove very rewarding for the decorator.

Furniture Arrangement.—It is a mistaken notion to think that one must have the benefit of spaciousness and the advantage of vistas in order to build rooms faultless in design qualities, efficient in furniture arrangement and beautiful in effectiveness. Particularly since these prime requisites are lacking in small houses and apartments. The procedure therefore is one of overcoming limitations in order to produce a pleasing effect. And the best means of doing this is through a consideration of the room's arrangement of furnishings.

Any interior worth assembling will present technical difficulties for the decorator, since every room has certain fixed requirements for family activities requiring specific items of furniture. From these activities groupings of furniture begin and the particular arrangement in the room is the natural result. Traditional furniture follows,

usually, a set pattern that seldom deviates, whereas in modern design variability is the rule, with furniture arrangement adapted to living habits. Naturally there is no basic design application.

The importance of the fireplace in either a traditional or contemporary room cannot be over-emphasized. The mantel, if there is one, should be in proportion to the room and not made merely to fit the fireplace opening. (The size of the opening is in direct ratio to the size of the flue: the smaller the flue, the less cost, hence the majority of fireplaces are too small for the size of the room. The difficulty can be overcome by adding facings of marble or stone.) The proportions of the mantel to the size of the room varies with the styles of period decoration: the Colonial style is characterized by big mantels in small rooms; the French styles, by contrast, have small mantels in large rooms; the English styles strike a happy medium, with mantels neither too large nor too small for the rooms in which they are installed.

ture within the areas allotted for various activities, being careful not to allow one group to interfere with another. This plan leaves the center of the floor clear, and the room gains in spaciousness. Disregard corners, and add pictures, sofa pillows, and other accessories at the last moment, reducing them to the absolute minimum in order to keep from crowding the effect. (See Floor Plan C.)

The problem of a long, narrow room can often be solved by altering the proportions. This is accomplished by dividing the long room into two separate groupings without sacrificing its unity and composition. (See Floor Plan A.)

The dining room, because it is occupied only during infrequent intervals of the day, offers an opportunity for a more dramatic decorative treatment than do the more lived-in rooms.

Finally, when planning the furniture arrangement of a room, fulfill all immediate requirements, but allow for future expansion. Such a plan is called the total design approach, because all immediate requirements are combined with any

Suggested furniture arrangements for one-room apartments.

Start with a floor plan of the room, drawn to scale, with all its undesirable features—such as doors opening into the room, windows too close together, radiators, etc.—indicated. Next, take advantage of the room's best feature—usually a window with a view, a fireplace, or a wide wall space where an important item such as a break-front desk or a television cabinet will be set—and add a sofa, coffee table, and chairs with accompanying tables for lamps, being certain to keep all traffic lanes clear; to this center of interest, add such secondary groupings for furniture as a table and chairs for games, or a television set that can be seen from every angle of the room. Large furniture items, such as a piano, breakfront desk, or sofa, should be kept parallel with the walls, and never catercornered, with a grouping of chairs and accompanying tables centered around each to form an interesting composition. (See Floor Plan B.)

Avoid crowding the plan, and arrange furni-

ture within the areas allotted for various activities, being careful not to allow one group to interfere with another.

Acquiring the more expensive items gradually over an extended length of time, and supplementing them with the cheaper furnishings, is recommended where there are budget limitations.

Budget Limitations.—The decorator should be aware of the value of furnishings as an investment, but at the same time expect returns from them in terms of durability, beauty and enjoyment.

Where restricted living space and limited funds force the newly-married couple, the bachelor, or career-bent girl each into the one-room apartment, the functions and purposes of furniture have to be combined. All one-room apartments can be divided into three parts: storage, dining, and living areas. (See Floor Plan D.) But far from being conducive to the state of confusion, one-room living can be very satisfactory from every point of view: a sofa by day becomes a bed at night; a chest of drawers is used to store linen

or as a sideboard; a table is used for games, for studying, and for dining. In this way space is conserved, making more activities possible in a specific area. In the same way, a guestroom that combines a living room with the comforts of a bedroom represents the ultimate in hospitality.

The first step in assembling a room for one-room living is substituting for the bed a couch with throw and pillows, or sofa-bed; otherwise the room will not be convincing. Accent pillows in harmonizing fabrics complete the room for day-and-night use. And there need be no sacrifice of either beauty or good taste for an attractive result. Instead of mahogany or walnut furniture in expensive finishes, natural woods such as birch, pine, or maple are selected; a harmonizing color scheme is enlivened with growing plants, and accessories are kept to a minimum, being limited to a few purposeful things such as a large mirror and attractive lamps. For the deadly foe of one-room living is senseless clutter. The color scheme will be a bright one, but it will be kept simple: green and white, pink and yellow, or lilac and blue, being a few combinations that are smart without any price connotation.

Whether the small house or apartment developed within budget limitations is contemporary in style, or follows a precedent of traditional design, is a matter of personal preference. New products offer an endless variety of home furnishings with which to create decorative schemes never possible heretofore except in expensive furnishings. There are, for example, inexpensive fabrics distinguished by textures and patterns applicable in either traditional or contemporary ensembles, and imitation leathers and modern plastics, resembling fine woods and marbles, which can be used for table tops, as well as paneling.

The folly of attempting to decorate a room—any room—without a plan of expenditure will be made more and more evident in each step of its development. The decorator should first compile a list of expenditures which provides only for the necessities absolutely fundamental to the development of the decorative scheme; but a supplementary list should also be made to accommodate any alternatives which may be used in the scheme as it progresses, as well as any additions to be made later if the budget is expanded.

In efforts to achieve charm inexpensively, interior decorators are more and more employing the painted background as an effective foil for lovely furniture and color schemes. They know from experience that decoration in its best phase is not dependent upon embellishment. And inasmuch as simplicity is the main characteristic of the contemporary style, it is the favorite resort in creating budget rooms. Another reason for the contemporary style in budget decoration is that it combines so easily and dramatically with traditional items, old furniture being especially effective with decorative objects and backgrounds in the modern manner.

In seeking individuality for the interior, the decorator should not be timorous either in his budget or decorative plan even though it may be for a budget room, for the resultant charm may depend upon maintaining a certain balance throughout for a particular effect. Strive for spontaneity and originality. Certainly price is the last thing a budget room is to suggest.

If the budget permits but a small outlay, it should be distributed proportionately so that money is spent where it will insure the most

value, as in the furniture or the floor covering. Unless an eye is kept on the budget, however, there may be a tendency here to overspend on a single expensive item—such as a rug or sofa—leaving only a small balance remaining for expenditures. Therefore where there is a limited amount allotted for a room, it is better to buy all items in proportion to the total budget.

Although wall finishes are expensive and difficult to change frequently, do not eliminate structural changes from the limited budget without first giving them deliberate consideration. Usually they supply so much architectural interest that, in the room being decorated for permanence, more expensive items such as imposing cabinet furniture can be eliminated for later incorporation.

There are occasions when fine woodwork, doors, mantels, and other details give a definite architectural character to a room and dictate expensive, permanent furnishings, but in rooms with no tendencies to any particular period, it is sometimes a matter of expediency in saving money to establish style interest by substituting inexpensive, relatively impermanent materials and finishes for more expensive ones. Thus standardized moldings and trim can be substituted for expensive handcarved woodwork; wallpaper, plywood paneling, or wood veneer on a paper backing, for expensive wood paneling; marbled and quilted effects printed on wallpaper can substitute for the genuine materials; embossed wallboard, sheet tiling, and enameled brick in tile patterns, for tile and mosaic; and linoleum, vinyl, or rubber tile, or asphalt composition flooring for marble.

Likewise where large items of furniture may be out of scale with their background, even in the pretentious interior, simpler and smaller pieces in natural finish, painted and decorated, may be substituted with pleasing results.

Slipcovers can transform old upholstered furniture by concealing its defects and adding fresh pattern and color, and they can also save one quite a sum of money when used on new muslin-covered furniture as a substitute for expensive permanent upholstery covering.

Lighting the Home.—In any decorative scheme the first consideration is the assurance of ample light: windows by day, and lamps by night. The light in a room is therefore an all-important part of the scheme, whether during the day or night, where it must be useful, yet decorative. In planning the room's illumination, the first thing to consider is the light sources, consisting of the lamps and lighting fixtures that are used.

These light sources should be as much a part of the scheme as are the draperies, furniture and rugs. In traditional rooms they should be related in style, decorative treatment and general composition to the rest of the furnishings. Authentically-designed period lighting fixtures and lamps (see LAMP) are available in the market, and antiques can be superbly adapted to electricity. In the contemporary room the fluorescent tubular lamp, installed behind window draperies and cornices, as well as concealed "down-light" fixtures in the ceiling, mean great adaptability in architectural lighting resulting in rooms notable for their decorative charm. Indeed with an acquaintance of the simple characteristics of light, and creative imagination, any room can be made a lovely place. For example, since mellowness is the chief quality desired in lighting, wax candles combined with

Enclosed porch decorated by Neiman-Marcus is given individual treatment in contemporary style, with painted brick floor, specially designed furniture, and contrasting color in casement curtains, upholstery and painted shingle wall.

electricity constitutes the ideal form of illumination for dining; shaded side lights will give a diffused light to the room and unshaded flames of tall candles on the table above eye level will contribute a festive glow that is most desirable.

Windows.—Windows are sources of light in the room and should be treated accordingly for maximum efficiency. Therefore drapery treatments should be kept as simple as possible. Windows are also the room's most important single decorative feature, because they can mar its friendly aspect or be depended upon to give an appearance of cheer and welcome. Because so much importance is attached to windows, too much attention cannot be devoted to their decorative treatment.

Windows are a special problem because, whether they are treated as an integral part of the scheme or simply as a part of the background, they are generally too high, too low, too narrow, unevenly balanced on a wall space, or are associated with radiators and air-conditioner units that protrude beyond them.

The low window can be given an appearance of greater height by merely hanging the draperies and curtains to the floor; or the draperies can be hung above the window frame and the space between the top of the window and the rod covered with a valance or cornice. The narrow window can be made to appear wider by hanging the draperies a few inches out on the wall at

both sides and covering the top of the curtains with a valance or cornice. If the window is unevenly balanced on the wall, draping the entire window wall from ceiling to floor and wall to wall will give the wall a semblance of architectural balance.

Corner windows are treated in the same manner as the low window: that is, framed with a simple cornice and with draperies hung at the sides; the window space, in every case, can be filled in with either sheer curtains or blinds. The bay window is usually a special problem that can be best treated with a valance connecting draperies at either side of the outer windows, and Venetian blinds or sheer curtains filled in underneath. An equally pleasing, but more architectural, effect can be gained by filling in the window areas with two tiers of louvered shutters or café curtains.

Clerestory windows in contemporary houses, as well as small high windows flanking a fireplace in old-fashioned houses, are always simply curtained with a sheer fabric or louvered blinds, without draperies, making them blend as much as possible with the walls. If radiators cannot be moved to some other place in the room or concealed with built-in covers, or if there is an air-conditioner in the window opening, the usual solution to the problem is to hang café curtains on the trim, halfway up the window, and allow them to hang straight to the floor, concealing the

radiator and air-conditioner unit; then upper panels of café curtains are added, or draperies are hung over the trim in the customary manner to the floor, over the first café curtains.

Draperies refer to the heavier fabric hung over the window frame, usually to the floor, and generally with a neutral color sateen lining. The curtains, to assure privacy and temper the light, are usually of a sheer material hung under the draperies, or in place of the draperies, and include such fabrics as casement cloth, organdy, net, dotted swiss, marquisette, thin muslin, or silk gauze.

Windows with draperies, plain or patterned, are more suitable for formal rooms, either traditional or contemporary in style, while ruffled or tiered curtains, used alone, are best used in simple rooms of provincial character.

A consideration too often given little thought is the matter of window shades in their relation to the street and to the exterior of the house. The interior naturally should dictate the choice of shades, but the face of the house should be borne in mind at the same time and shades chosen that will harmonize with both exterior and interior. Blinds include Venetian blinds, bamboo and matchstick blinds, as well as louvered shutters, and are best considered as part of the background of the room, and painted a neutral color blending with walls or curtains. Roller shades can be of textured fabric, to give them a new look, or they can gain in decorative value by being made of fabric to match the draperies. Roller shades, if made of patterned chintz, can be a distinctive decorative feature when they are combined with crisp ruffled sheer curtains—and no draperies are then needed.

Kitchens.—Although a kitchen is primarily a workroom, it need not be coldly efficient. And it is a myth that color is not appropriate in the kitchen, because examples in strong color contrasts—such as yellow with bright green and splashes of red on tables and chair seats—have resulted in the kitchen being the most attractive room in the house. Enameled equipment and washable wall surfaces have a high reflective power which increases the brilliance of any color. Color in the kitchen is an even more important factor in its decorations if the family eats there. Pictures on the walls, and fruits and vegetables in still life compositions are fresh ideas for kitchen decoration.

Each fundamental part of equipment in the kitchen must be assembled in an organized manner. Arranging the compact units that are on the market is, of course, regulated according to the size of the room in which they are used, which in turn depends on the number of members in the household. Sufficient space is available, it will seem, only when starting from the blueprint; but in remodeling it can readily be achieved by centering units or changing doorways and partitions to produce a workable area combined with good design. Working tops of laminated plastic material, on low cupboards and tables, are burn, stain and scratch-proof and can quickly be cleaned by wiping with a damp cloth. Standard sizes are available in storage equipment, but those units that are made to measure give the decorator greater scope in attaining balance or in expediting the arrangement according to the conditions present.

Porches and Terraces.—Porches, including breezeways, terraces, and patios, are considered

an extension of the house, and as such have a decorative relationship with it, the only difference being that the outdoor room receives a less formal treatment than the indoor living room.

For the terrace or porch an appearance of spaciousness is desirable, because nothing is more enervating than a crowded effect outdoors of a warm day. Furniture groupings are distributed around the walls and never in the center, and passages to the living room and to the garden are never obstructed by chairs or tables.

Furniture on the porch or terrace receives the same consideration for convenience and adaptability to comfort that it would indoors: a table with an umbrella, and a pair of chairs at the far end of the terrace, a glider swing and several occasional chairs; a table and chairs for cards; a covered chaise-longue on wheels; a table beside a chair for a book and refreshments. Sturdy, weatherproof reed and rattan furniture is smart in appearance and serviceable, and can be fitted with waterproof cushions; metal furniture that can be easily moved about is especially good when combined with reed or rattan items. For the rustic setting, the furniture made of hickory, either peeled or with the bark left on, is ideal.

For the outdoors a color scheme should be decided upon that is bright and clear, one which will make the terrace appear cool and livable during the warm months. White combined with yellow, green, blue, red, or brown constitutes a highly satisfactory color duet to enliven the scene and repeat the colors of the garden. Awnings may accentuate these hues in stripes or in solid colors.

Sculpture, the most permanent feature in decoration for the garden, terrace or porch, may assume decorative figures, fountains, architectural elements or such usual forms as vases and urns for interest. Because of its importance in the scheme, sculpture should be carefully selected and placed in strategic spots.

The Child's Room.—Because the child's room must keep pace with a growing youngster, developing along with him, it is probably the only room in the house that goes through several metamorphoses. Therefore buying furniture with an eye to the future is the most sensible plan. The functional contemporary ensembles of cribs, chests and chairs can be used as the child grows older. And manufacturers offer cribs that can later be transformed into beds, and chests which can be fitted together to make cabinets and desks to fit the needs of the older child. A bassinet on wheels is ideal for the baby; whether it will be all flounces and frills or merely plain and practical depends upon the budget. Period furniture is appropriately used in the child's room provided some forethought is given to the selection. For example, a small desk or chest in a period style can be the beginning for the older child's group of furniture. It should be remembered that all the furniture is for the child's use and should be scaled and designed proportionately. A high chest of drawers, the top of which the child can scarcely see, let alone reach, is likely to be bewildering. Chairs, mirrors, and chests should be usable and not make the child feel dwarfed. Washable wallpaper or one of the synthetic wall coverings will not only satisfy the practical side, but be decorative as well. Linoleum, in appropriate colors and patterns, is always good as a flooring in a child's room; if a rug must be used, a washable throw rug over it will complete the

scheme. Accessories deserve special consideration, and if they are hazardous they have no place in the room. If furnishings are wisely chosen in the early years, little will have to be discarded when the teen age arrives.

Finishing Touches.—Smart accessories complete the decorative effect in every room. If the effect desired is one of elegance—and elegance is the note most evident in many apartments and suburban homes—it is important to choose accessories consistent with the theme of elegance established by the other furnishings in the room. Perhaps what will be needed will be examples of exquisite porcelain, a decorative wall panel painted in oils, or an unusual flower arrangement to give the final note. In the informal room, or one without a “decorated” look—such as an early American, Provincial or a small-house type of interior—the accessories will be of simple character and more familiar forms, including hand-thrown pottery bowls and vases, handblown glass and decorated wooden boxes. Choosing these accessories and placing them correctly is the last important phase of interior decoration.

2. CONTRACT INTERIOR DECORATING

The contract interior decorator must not only be a qualified residential interior decorator, but he must be thoroughly acquainted with hotel and institutional operation—including schools, hospitals and banks—as well; he must also be aware of the special requirements for stores, transportation, offices and theaters. His attitude and approach to each problem is therefore different, because he has to cater to a wide cross-section of people, which may include the traveling public, the shopping public and the theater-going public. Individual whims have to give way to the satisfying of mass tastes. Yet it is still the duty of the contract interior decorator to hold the restraining hand in matters of style and good taste.

Stores.—The significance of decoration as a powerful stimulus to sales grows apace with merchandising, a fact evident in the strides which have been made in both the wholesale and retail fields during the past decade as store owners have come to realize that their clients prefer shopping in an attractive, pleasant atmosphere.

The decoration of a store or house is governed by the same basic principles. Reducing these basic principles to their simplest terms, it can be said that the interior of a house serves, first, as a background for gracious living, and second, as a mechanism for one's living. This means that as a background, color, type of fabrics, furniture, floor coverings, lamps and their arrangement, draperies, and other decorative factors are employed to create a visual effect. As a mechanism for gracious living, the design and disposition of the furniture, lighting, textures of fabrics and all the other elements which make up a room, are the main considerations. The store interior can also be considered in the same manner; it is primarily a mechanism for storing and displaying merchandise and, secondly, a background or stage for sales. For selling, the requirements include units for storing merchandise for sale, making it easy to be seen and examined by salespeople and customers with little difficulty, and including such items as shelving, bins, cases, drawers, racks, tables, counters, and chairs suited to the various types of merchandise. When the problem is one of modernizing an old building, the interior decorator begins an intensive program of com-

pletely reorganizing the various sales departments, including their architectural backgrounds and color schemes, as well as furnishings. Dramatic effects are achieved by various original devices of design, lighting and use of decorative materials. Before beginning the design of a new store interior, the decorator must be thoroughly familiar with the type of merchandise to be sold. In the volume-type of store the merchandise must be stored so that it can easily be seen and examined by the customer and the clerk; in the more exclusive shop, there is a tendency to keep merchandise out of view, the clerk bringing out the various articles for the inspection of the purchaser. The decorator also studies the individual merchandise, and designs cases and cabinets according to the requirements of each. Counters and tables are also designed to suit their own particular function; not only should the cases be designed to be decorative, but the merchandise itself should be so arranged that it forms a pleasing ensemble. An interesting arrangement can make drab merchandise, even shoeboxes, take its place in the decorative scheme. If the principles for merchandising are thoughtfully worked out, the decorator will find that the problem is not only to take the counters and racks and design them as individual units, but to create a background for them so that the entire store becomes a stage for selling. This means that the merchandise must be dramatized by the use of decorative materials, color and lighting. For, aside from its advertising value, an interesting and exciting store interior results in additional sales.

Offices.—If the office is to be workable it first must be made livable. When one realizes that the average businessman spends a third of his life in his office, it becomes clearly evident how essential this quality of livableness really is. The office must also acquire personality. This depends upon its livability; and if this quality is attained, there will be realized a fine air of dignity and comfort. After the functions of the various departments of a business have been studied in the preliminary plan, and a relative share of space allotted to each, the logical solution to the problem of selecting furnishings can then be determined. The first essential step here will be to ascertain the type of interior decoration that is desired, and whether it reflects the nature and personality of the business. The average office is concerned with today's business, and therefore requires nothing traditional in the manner of its decorative treatment; however, the personal taste of the owner may demand an office developed in one of the historical styles. When one realizes how very different one office can look from another, and that the difference is attributable entirely to the styling of its decorative treatment, then it is evident how important style is in designing offices. Decorating an office includes the selecting and placing of furnishings, but, more important, the designing and installing of architectural backgrounds in sympathetic relation to the types of furniture and the needs and personality of the business as well. Therefore the efficiency in functioning of the office will be an important consideration. Individuality in offices may be attained in various unusual ways by means of such materials as metals, wallpaper resembling paneling, cork, paint, leather, linoleum, glass, vinyl tiles, glass or plastic fabrics used on the walls. The windows may have Venetian blinds or vertical fabric louvers instead of cur-

tains, and the floor may be of rubber tile, linoleum or cork, with or without rugs laid down over it. Furniture in the office may heighten the contemporary designing with upholstery in modern synthetic colorful fabrics. Wallpaper and photomurals showing scenes in a firm's factory are important means of conferring individual interest upon backgrounds. Nothing will aid so much in making an office gain in quiet repose as the alteration of objectionable architectural details such as piers, door openings and overhead beams, into a balanced symmetrical arrangement of background areas. Sprinkler system outlets and ceiling beams can be eliminated by furring down the ceiling, but if this is impractical, false beams can be added to balance the existing ones which happen to be off-center. Where an off-center door cannot be changed, a balanced effect can be obtained by placing a symmetrical, but false, twin in the same wall; in the same manner, a window that does not give sufficient light or is disturbing to the architectural composition may be eliminated by covering it with a Japanese shoji panel, illuminated from behind, if in a contemporary room, or covering it with a panel matching the wall and eliminating it altogether but leaving the glass and mullions undisturbed.

Restaurants and Cocktail Lounges.—The contract interior decorator commissioned to decorate and furnish a restaurant or cocktail lounge has a greater responsibility than merely the creation of a beautiful background. He must produce a furnishings plan, and reckon with a fickle public demanding easy traffic lanes, comfortable seating furniture, easy access to checking facilities, rest rooms and a score of other conveniences never encountered in residential planning. He must also provide quick service by the restaurant staff; and this calls for proper location of pantries, food checkers and service bars—all with an eye upon the size of the investment. There should be a definite relationship between the quality of the furnishings and the character of the patronage to be served: the night club represents the more sophisticated interior, but the tea room, the chop house, the chain restaurant, each represents its own degree of sophistication, also. Appropriateness of style, quality and cost for each type of operation, are therefore the principal conditions which should govern the effort of the interior decorator if he is to produce for the owner a proper return on his investment. Restaurant furniture must be designed to give the utmost sturdiness consistent with good proportions; the quality of the carpets, china, silver and glassware must stand up under the vicissitudes of public use. Repairs and costs of replacements affect maintenance expenditure so that profits can quickly disappear if the interior decorator overlooks this important factor. Therefore contract decorating invariably represents a compromise between the most desirable materials and the minimum cost, as well as between the most impressive decorative effect and maintenance, and between the most attractive colors and durability.

Schools and Hospitals.—In the decorating of schools and hospitals and other institutions there has to be borne in mind the fact that maintenance budgets are invariably low, and therefore the interior decorator must exercise care that he does not overlook practicality. In private schools, colleges and universities there are many types of classrooms naturally not existing in the elementary and secondary public schools, and each pro-

vides its own problems. Furniture, fabrics and other materials should be considered carefully for durability. In classrooms, the color of the walls should reflect the maximum amount of light without being in a glazed finish; and where blinds are used, they should be the same color as the walls. An attractive scheme may have dado, metal parts of desks and trim in the same color, with the walls and ceiling a light complementary color; and if the floor is rubber or asphalt tile in color, it may be brought into the decorative scheme also. Rooms on the north side of the building may, with good effect, be made warmer in color. Auditoriums offer special problems, for here hard wear is at its worst. A wainscot is essential, and it should be of a durable material. The ceiling and walls should receive acoustic analysis, and the materials chosen will enter into the decorative scheme. Flooring for the aisles should be selected for quietness, and, if sloping, a slippery surface is to be avoided. The problem of decorating interiors for schools offers intriguing possibilities as well as serious responsibilities inasmuch as the quarters in which maturing students work and play may well have a vital influence on their later lives, because the artistic taste of many of these young people is being formed at school far more than it is at home. Invariably the architectural background will set the style, but the interior decorator must also be governed by the need for simplicity, durability and ease of upkeep.

Hotels and Ships.—The first essential step in decorating the hotel or ship (for the average de luxe steamship resembles a hotel in many ways) is to ascertain the function of the various rooms to be decorated and to apportion each, depending upon its importance, a relative share of the allotted expense in the estimate. Once the purpose of the space is established, a logical solution can then be reached in the problem of furnishings. The great metropolitan hotels that offer sophisticated activities naturally will demand spacious and luxurious settings which are unsuited for the commercial hotel catering to a general patronage requesting merely pleasing surroundings. Between these two types lies the medium for the smaller residential hotel. Lobbies and lounges give the guest his first impression, therefore it is essential that they be as attractive as possible. The plan should provide an air of spaciousness in order to relieve any feeling of crowding, and one group of furniture should not interfere with another. Much of the dignity of the public rooms will depend upon the draperies and carpets. Expensive furniture and textiles lose their effectiveness by bad groupings and inharmonious color schemes. Simple, straightforward formal groupings without benefit of pictures, sofa pillows or small mirrors should be the rule. The decorative possibilities of halls and passageways should not be overlooked; settees and benches and console groupings, with accompanying pictures and lamps—either to break a long wall or to form a focal point at the end of a corridor—will contribute much charm. The restaurant, because it is occupied only during infrequent intervals, offers an opportunity for a more dramatic decorative treatment than does the lounge or lobby. The expanse of white in the dining room, in the napery, can be counteracted by draperies and wall covering and by colorful china; or it can be turned into a decorative advantage. Creating guest-rooms which are practical as well as attractive

requires the decorator's best efforts, because every decorative scheme is multiplied throughout the various rooms. Although the furniture will be simple of line, assertive notes of color will appear in bedspreads, draperies, lamps and the upholstery. The complicated problem of color schemes for a vast number of rooms is very simply solved by specifying draperies, carpets and bedspreads which can be used interchangeably throughout, provided there is no feeling of monotony. Transient guests require rooms in which comfort with charm is the distinctive note, but in many hotels the decorator will have an opportunity to employ door beds, dressing closets and sofa-beds to advantage in enabling the guest to convert the room which functions as a living room by day into a bedroom at night. China, linen, carpets and draperies for use in a hotel demand special consideration; therefore furnishings for minimum depreciation should be selected, with their practicality as well as beauty considered. Another matter to consider in relation to the depreciation of furnishings is their renovating and maintenance. The selection of drapery and upholstery fabrics will be particularly affected, and careful thought must be made of textures as well as colors and patterns. Other items to be considered in the upkeep expense include carpets, bedspreads, linen, wall coverings, woodwork and furniture.

Transportation.—In the office of the interior decorator, decoration for transportation proceeds from a thorough study of current and future trends. By expressing the romance and luxury of travel, the contract interior decorator dramatizes the quality of service offered passengers. This is accomplished in a different manner for each form of transportation. Interiors for ships are cruise-conscious, with forms and colors stylized and adapted from shipping and marine motifs setting the spirit; for air travel, speed, lightness and safety are emphasized, and colors are restful and textures are luxurious; train and bus interiors stress speed, comfort and dependability. Color psychology is exploited, with aesthetics of line, proportion and balance the real considerations; textures, materials and lighting arrangements are juggled to satisfy in the finished interior a cultivated appreciation of the appurtenances of comfortable travel. In airplane design, weight reduction is an important consideration, and decoration is successful insofar as it recognizes this factor. For example, by using specially designed lightweight carpet for floor covering, the greater weight of an equal amount of carpeting is eliminated, and more pay load can be carried and the margin of safety increased. Soothing color schemes and lighting are used to calm the hyper-nervous air traveler. Illumination presents difficulties, since the plane must carry its own source of generating power; and efficiency is paramount since the wattage is necessarily lower. In decorating for aircraft, the added exigency of weight reduction in this lighting system is a major factor. All ocean lines, airplanes and trains must, of course, be fireproof, therefore metal furniture and fireproof fabrics are specified. Careful and extensive research into the limitations and possibilities of these and other less commonly used materials is incumbent upon the designer. For ships, floor coverings are specified which will not be slippery in a heavy sea; and metal finishes must resist the ravages of salt air.

INTERJECTION, ʔn-tēr-jěk'shŭn, a word thrown in, to express some sudden emotion or passion; an exclamation such as ah! alas! ouch! Interjections are hardly considered parts of speech and never form grammatical parts of a sentence; they are rather direct expressions of feelings which articulate speech attempts to describe or define. See also GRAMMAR—*Parts of Speech*.

INTERLAKEN, ʔn'tēr-lä-kěn, or ʔn-tēr-lä'kěn (meaning "between the lakes"), town, Switzerland, in Bern Canton, 26 miles southeast of the town of Bern. It is beautifully situated near the left bank of the Aare River in the valley of Böödel, between the lakes of Thun and Brienz. It is the largest resort in the Bernese Alps. The main street is famous for its view of the Jungfrau. Industries include the manufacture of woolen textiles and printing. It contains a beautiful old castle and numerous hotels and is the starting point for many tourist excursions into the surrounding Alps. Pop. (1954) 4,368.

INTERLUDE, ʔn'tēr-lŭd, in drama, a sort of play popular in the 15th and 16th centuries. It was the successor of the morality play (q.v.) and differed from it chiefly in being shorter and prevalently comic in tone, often to the point of farce. It too relies, particularly in early examples, on allegorical characters. John Heywood, a courtier-wit in favor with Henry VIII and Mary I, was the first considerable writer of interludes. Some of his best pieces, in which Sir Thomas More was possibly a collaborator, veer close to Ben Jonson's excellence in comedy-farce. Easily performed by amateurs, even by villagers for the amusement of the lord of the manor, the interludes won a grateful public who relished their broad humor and attacks on great men disguised as types.

Much has been written on the origin of the term. Probably Sir Edmund Kerchever Chambers rightly considered it a play (*ludus*) between (*inter*) two or more actors. Eric Partridge, in *Origins*, has for *interludium* "a game between two periods of business"; the business could be a long morality play or some official occasion.

WALLACE BROCKWAY.

INTERLUDE, in music, generally a piece played either between other pieces or between sections of a single piece. Although applied loosely to entr'actes, *intermedii*, *intermezzi*, and even wholly independent compositions of tentative or intermediate nature, the word has a specific meaning as applied to brief organ improvisations heard between strophes or verses of a psalm or hymn in Roman Catholic churches from the early Renaissance forward. Somewhat related improvisatory interludes were at times played between lines of a chorale in Protestant churches, notably in Germany, a familiar composed example being Johann Sebastian Bach's *In dulci jubilo*.

HERBERT WEINSTOCK.

INTERMENT. See BURIAL; DEATH CUSTOMS AND RITES.

INTERMETALLIC COMPOUNDS, in-
tēr-mē-tāl'lik kōm'pōundz, combinations of two or more metals representing a particular atomic ratio, such as GaAs or AuZn₃. They are generally markedly different from pure metals or solid solutions of the component metals. The compounds are usually hard and brittle substances, and the electrical conductivity is often low compared to the elemental metals. Because of these quasi-metallic properties, the intermetallic compounds are important as semiconductors and useful constituents in many alloys, where they act as hardeners. Since the ordinary rules of chemical valence and stoichiometry are often violated in these materials, it is apparent that the chemical bonding in intermetallic compounds is unlike that in such compounds as NaCl. On the basis of the bonding, there are three different categories of intermetallic compounds: *electron compounds*, *valency compounds*, and *interstitial compounds*.

Electron compounds exhibit specific electron densities. The British metallurgist William Hume-Rothery (1899—) observed that valency electrons to atom ratios of 3:2, 21:13, and 7:4 exist in a large number of intermetallic compounds. Examples of the 3:2 ratio are CuBe and Cu₃Al, where copper has one valence electron and beryllium and aluminum have two and three respectively. Other examples are Cu₃Cd₂ (21:13 ratio), and Ag₃Al₂ (7:4 ratio). Electron compounds generally exist over a range of composition, and the bonding is essentially metallic. They are often good electrical conductors. Some are plastic, but those having complex structures such as Cu₃Al₂ are brittle.

In the valency compounds the normal rules of chemical valence apply. The atoms may be held together by either ionic or covalent (homopolar) bonding or a combination of both. In the ionic compounds one metal atom tends to give up its valence electrons to the other. This requires a marked difference in the electronegativity of the atoms. Examples are MgSe, BaTe, and Mg₂Pb. In the covalent compounds the atoms tend to share the electrons, often in a tetrahedral bond arrangement. Elements of Group III and Group V frequently form covalent compounds such as InSb and GaAs. Valency compounds are generally semiconductors, and are usually hard and brittle.

The interstitial compounds make up a very important class, in which size factors are significant. There are often large differences in the atomic diameters. Although carbon and nitrogen are considered nonmetals, the carbides and nitrides of the transition metals are classified as interstitial compounds. They are very hard and brittle materials, having high melting points. The hardness of many alloys is due to such interstitial compounds as Fe₃C, Fe₃N, WC, and MoN. In the case of the transition metals, the bonding appears to be metallic, and the compounds are electrical conductors. In the case of the more electropositive metals the bonding may be valency, and such compounds as CaC₂ and BaC₂ are poor conductors.

Research Associate in Physical Metallurgy, College of Engineering, University of Illinois.

INTERMEZZO, in-tēr-mēt'sō (Lat. *intermedius*, intermediate), in music, a term with several applications. In the 18th century, *intermezzi* were brief comic episodes sung between acts in *opere serie*. Becoming detached from the parent operas, they evolved into *opera buffa*. The famous *La serva padrona* of Giovanni Battista Pergolesi was at first an intermezzo between the acts of his serious opera *Il prigionier superbo* (1733). In the 19th century, the word was applied (1) to independent brief piano pieces of rather informal nature (Schumann, Brahms), perhaps because they were composed between pieces of greater importance, an idea related to Beethoven's use of the term for a linking movement in his "Waldstein" Sonata in C major, opus 53; and (2) to orchestral entr'actes in operas (as in Pietro Mascagni's *Cavalleria Rusticana*, 1890, and Giacomo Puccini's *Manon Lescaut*, 1893). Richard Strauss' opera *Intermezzo* (1924) was so called because of the parenthetic character of the events of its libretto.

HERBERT WEINSTOCK.

INTERNAL COMBUSTION ENGINE, in-tūr'nāl kōm-būs'chūn, a heat engine in which the fuel is burned (that is, united with oxygen) within the confining space of the engine itself. This burning process releases large amounts of energy, which are transformed into work through the mechanism of the engine.

This type of power plant differs from the steam engine, which uses an external combustion process because its fuel is burned apart from the engine (and under a boiler to convert the water in the boiler into steam, which then flows to the engine to expand and do work).

In general, it cannot be said that the internal or the external combustion process is inherently more efficient. As a practical matter, the internal combustion engine has the advantage on the high-temperature side, while the external combustion or vapor cycle does better on the low-temperature side. In most cases, it may be obvious which type of engine would be more efficient, but sometimes a complete analysis may be required.

In general, the internal combustion engine has become the means of propulsion in the transportation field, with the exception of large ships requiring over 4,000 shaft horsepower (hp.).

In stationary applications, size of unit and local factors often determine the choice between the use of steam and diesel engines. Diesel power plants have a distinct economic advantage over steam engines when the size of the plant is under about 1,000 hp. However, there are many diesel engine plants much larger than this. Internal combustion engines are particularly appropriate for seasonal industries, because of the small standby losses with these engines during the shut-down period.

History.—The first experimental internal combustion engine was made by a Dutch astronomer, Christian Huygens, who, in 1680, applied a principle advanced by Jean de Hautefeuille in 1678 for drawing water. This principle was based on the fact that the explosion of a small amount of gunpowder in a closed chamber provided with escape valves would create a vacuum when the gases of combustion cooled. Huygens, using a cylinder containing a piston, was able to move it

in this manner by the external atmospheric pressure.

The first commercially practical internal combustion engine was built by a French engineer, (Jean Joseph) Étienne Lenoir, about 1859-1860. It used illuminating gas as fuel. Two years later, Alphonse Beau de Rochas enunciated the principles of the four-stroke cycle, but Nikolaus August Otto built the first successful engine (1876) operating on this principle. (See Fig. 1.)

Fig. 1. Model of engine on which Otto secured his American patent in 1877; now in the Smithsonian Institution.

This engine also burned illuminating gas, but with increased efficiency because of compressing it before ignition. Otto secured an American patent in 1877.

The advantages of compressing the charge before igniting it were probably discovered by an Englishman, William Barnett, who patented the idea in 1838. Barnett also pioneered the two-stroke cycle, but Dugald Clerk, a Scottish engineer, contributed the most to its early development—to circumvent Otto's patents.

In 1892 Rudolf Diesel, a German, conceived the idea of igniting the fuel by injecting it into air that, by compression, had been heated to a point where its temperature would start combustion. Since then his name has been identified with the combustion or constant pressure type of engine, as distinguished from the Otto explosion or constant-volume type. (See Fig. 2.)

Fig. 2—Cross section of Nordberg two-stroke-cycle diesel engine for stationary applications.

Diesel's work was entirely with relatively large, slow-speed engines, but since his death (1913), high-speed diesels have been developed, employing a modification of the diesel cycle.

Contemporaneously with Otto's work in Germany, a Boston engineer, George Brayton, designed an engine to burn gasoline.

The means of igniting the combustible mixture passed through several stages before higher speeds and, hence, lighter engines could be made available for vehicles and boats. Otto used a flame to touch off the gas, and the best speed he could get was 150 to 200 revolutions per minute (rpm.). One of his workmen, Gottlieb Daimler, set up his own shop and developed what became known as hot-tube ignition. By regulating the heat of the tube, he could control the point at which ignition took place. In 1883 he succeeded in attaining 800 to 1,000 rpm.—speeds high enough to make the automobile practicable.

Fig. 3. Gas turbine patented in 1791 by John Barber.

Attention was then turned to the development of carburetors by which gasoline could be atomized or vaporized to substitute it for gas as a fuel, making the use of internal combustion engines possible in portable applications. Daimler in Germany and Fernand Forest in France both accomplished this in 1885. Daimler had the better engine, but Forest developed the better carburetor.

Daimler forced air through the liquid fuel, and the entrained particles, by contact with the hot tube, were gasified before igniting. Forest sprayed the fuel into a stream of air, on the principle of perfume atomizers or insecticide sprayers. Later, an associate of Daimler's, Wilhelm Maybach invented the float-feed carburetor, which has become the accepted form.

Karl Benz, another German, taking Daimler's engine and Forest's carburetor, installed them in a tricycle, adding electric ignition. In 1885 he built the first gasoline automobile, which quickly became and still is the largest field of applica-

tion of internal combustion engines. (See *AUTOMOBILE—Automobile Engine*.)

The principle of the turbine has been known for a long time. About 100 A.D., Hero, the Alexandrian philosopher, built a reaction turbine, which converted steam pressure into mechanical power.

This invention, as well as Giovanni Branca's steam jet-operated turbine of 1629, was the inspiration for later inventors in their attempts to substitute combustion products for steam as a more convenient method of power generation by means of a turbine.

John Barber was the most outstanding of these early inventors in his recognition of the possibilities of the internal combustion turbine. His patent of 1791 is the first recorded description of a gas turbine. (See Fig. 3.)

The next important step was taken by René Armengaud and Charles Lemale, who started building gas turbines in 1894, which it is claimed worked satisfactorily for several years, although at a low thermal efficiency.

By the beginning of the 20th century many other turbines were being built, such as the Stolze air turbine and the Holzwarth constant-volume gas turbine.

Other work was being done by Charles Gordon Curtis, who patented a gas turbine in 1895 and Dr. Sanford A. Moss, who, in 1902, was operating a de Laval turbine with the aid of combustion products.

The Britisher, Frank Whittle, is credited with having devised the first practical solution to the problem of aircraft propulsion by thermal jet reaction using a gas turbine-compressor unit. His original patent was dated 1930 although it

doing important research: Junkers, Heinkel-Hirth, and BMW (Bavarian Motor Works). Out of this work came the development of a jet engine that was installed in an HE-178 (Heinkel-Hirth). It flew in August 1939—the first jet-propelled aircraft to fly.

Fig. 5. Horizontal arrangement of cylinders is shown by this two-cylinder, four-stroke, air-cooled gasoline engine built by Outboard Marine Corporation. Producing 18 hp. at 4,000 rpm., it can be used as power source for utility vehicles, pumps, compressors, and the like. Shown here is the rear view (power takeoff end).

Classification.—The principal types of internal combustion engines are: reciprocating engines, such as gasoline, diesel, and gas engines; and rotary engines, such as the turbine engine.

Fig. 4. Arrangement of engine with vertical cylinders is shown by this four-cylinder, four-stroke, water-cooled gasoline engine built by Coventry Climax Engines, Ltd. (England). It produces 40 bhp. at 4,000 rpm., and is used as a fire pump engine.

Fig. 6. Chrysler Corporation's Slant-6 engine is a modern version of the inclined cylinder. The engine is tilted 30° for most efficient use of engine compartment space. It produces 145 bhp. at 4,000 rpm., and has many aluminum parts, the largest being the cylinder block.

was not until 1944 that an aircraft employing his ideas was actually flown by the British Royal Air Force and the United States Air Force.

Meanwhile, several German firms had been

Reciprocating Engines.—In the reciprocating engine, power is transformed into work by the reciprocating action of a piston. Piston engines come in all sizes from the tiny model air-

Fig. 7. Chrysler experimental gas turbine being developed for potential automotive, marine, and industrial applications produces 140 hp. The unit weighs 450 pounds, considerably less than a comparable piston engine. Top: The gas turbine installed in a Plymouth passenger car. Bottom: Cutaway view of the experimental turbine unit.

plane to large diesel engines of many thousands of horsepower. (See Fig. 2.)

Reciprocating internal combustion engines have been classified in many ways, such as:

(1) According to the ideal cycle that should be used as a standard of comparison with the real engine, such as the constant-volume cycle and the constant-pressure cycle.

(2) According to the number of strokes of the piston necessary to complete one power cycle: the four-stroke cycle and the two-stroke cycle. (A few highly experimental engines have also been built to operate on a six-stroke cycle, but none have been practical.)

(3) As to whether the engine is single acting or double acting; that is, whether the piston receives pressure on only one of its sides or on both sides. Most internal combustion engines are single acting, although a few double-acting ones have been built in large sizes for stationary applications. While the double-acting engines produce about twice the power of the single-acting ones of the same bore and stroke, there are mechanical difficulties in that limit the use of this type.

(4) According to the fuel used: gas, gasoline, or fuel oil.

(5) According to use: automotive, aircraft, marine, stationary, or portable.

(6) As to the arrangement, position, and number of cylinders. The axes of the cylinders may be vertical (Fig. 4), horizontal (Fig. 5), or inclined (Fig. 6). The cylinders of multicylinder engines may also be arranged side by side (Fig. 4), or they may be end to end (with pistons opposed, as shown in Fig. 5); they may be radial, or they may be inclined in banks, as in the V type of engine.

There are other variable characteristics that are often pertinent to the description of a given engine; for example, the method of governing, the method of introducing fuel into the combustion space, and the arrangement of the valves.

Rotary Engines.—Progress is constantly be-

ing made in the design and application of gas turbines for stationary use and for locomotive, marine, and automotive propulsion (Fig. 7) purposes, but the applications are either experimental or extremely limited. It is in the high-speed aircraft field that they have found their main application, where they have practically replaced the piston engine.

Gas turbines can be classified as follows:

(1) Constant-pressure turbine, in which the turbine wheel is actuated continuously by the products of combustion admitted from the combustion chamber. (Actually, pressure does vary under load changes, so a better name would be continuous-combustion turbine.)

(2) Explosion or intermittent-combustion turbine operating according to the constant-volume-cycle method. (An example is the German Holzwarth gas turbine.)

(3) Open-combustion-chamber turbine, in which heat is supplied while both pressure and volume are changing. (The Karavodine turbine built in 1908 is an example.)

The latter two types are little used today. The constant-pressure type has pretty well taken over, being used in aircraft, as well as most other turbine power plants.

There are three major types of aircraft turbine engine: (1) turbojet, (2) turboprop, and (3) turbofan.

These engines all have a gas turbine as an integral part of the design. Other types of aircraft or space vehicle engines having some form of turbine in their design include: the ramjet or athodyd, the rocket engine, and the pulsejet or flying bomb—the V-1 of World War II.

(For further information about aircraft power plants, see AERONAUTICS—4. *Flight Propul-*

Fig. 8. The Wankel rotating combustion engine has only two major rotating parts—the triangular rotor and the crankshaft (output shaft). As the rotor turns inside the housing, a fuel-air charge is drawn in through a fixed port, compressed, and ignited when it passes the spark plug. The expanding gases push the rotor around until they can exit through the exhaust port.

sion; ROCKETS; JET PROPULSION.)

Through the years many unusual types of rotary engine have been designed, and some of them have been built. A few of them even worked—after a fashion. In theory, at least, the rotary engine seems like a much better idea than the crude piston-rod and crank arrangement and the even cruder poppet valve device, but (except for the turbine engine) it just never seemed to work out. Then, Felix Wankel, a Ger-

man, came up with an idea for a rotary engine that, by the late 1950's seemed to have possibilities. Called the "rotating combustion engine," it consists of a housing with a wasp-waisted cavity within which an inner, roughly triangular rotor rotates, as shown in Fig. 8. As of 1961, only gasoline versions operating on the four-

Fig. 9. Free-piston engine produces hot gases formed by diesel combustion in the power cylinder. These drive the turbine, which, in turn, may drive the wheels of a vehicle.

stroke cycle had been built, but other types were contemplated.

Compound Power Plant.—Another type of engine is the compound power plant. Basically, it consists of a reciprocating engine plus some means—generally a turbine—for extracting energy from the exhaust gas and converting it into power.

One version of the compound engine is the free-piston-turbine engine. Here, as shown in

Fig. 9, the unit produces hot gases which are used to drive the turbine, which in turn can be geared to the wheels of a vehicle.

The Cycle.—The processes that take place in regular sequence in any internal combustion engine are as follows: (1) induction, (2) compression, (3) combustion and expansion, and (4) exhaust. When an engine goes through this series of processes once, a cycle is said to have been performed.

Although there are many types of cycles, the ones in greatest use today are (1) the Otto cycle, in which the fuel is burned at essentially constant volume (used mainly in gasoline engines); (2) the diesel cycle, in which the fuel is burned at constant pressure (used in low-speed diesel engines); and (3) a modified diesel cycle, in which the first portion of the fuel is burned at approximately constant volume and the last portion at nearly constant pressure (used in high-speed diesel engines).

The constant-volume and constant-pressure processes were originally developed for reciprocating engines, but modifications of them are also used in turbine engines.

In fact, although turbine engines and reciprocating engines are quite different mechanically, the series of operations is basically the same for both power plants, as shown in Fig. 10. The only real difference is that in the turbine engine employing constant-pressure combustion power is produced continuously, whereas in the reciprocating engine it is produced intermittently. (In the constant-volume-combustion turbine, power is produced intermittently.)

The operation of the reciprocating engine shown here (a four-stroke Otto cycle engine) is as follows: on the first downward stroke of the

Fig. 10. Comparison of rotating and reciprocating engines. In the lower series of diagrams, the four intermittent strokes of a reciprocating engine are approximately aligned with the four continuous functions of the turbojet engine above them.

piston, a mixture of fuel and air enters the cylinder around the open inlet valve. When the piston reaches the bottom of its stroke, the inlet valve closes so that on the return upward stroke the charge is compressed. When the piston reaches approximately the uppermost point of travel (top dead center), the charge is ignited by the spark. Then the expansion of the gases resulting from combustion forces the piston downward again for the power stroke. Finally, the second upward stroke of the piston drives the burned gases out of the cylinder around the open exhaust valve.

The turbine unit shown in Fig. 10 is an aircraft turbojet engine with a multistage axial compressor and a single-stage turbine. Air enters the front of the unit and is compressed by degrees as it passes through the several stages of the compressor. From here it enters the combustion chambers into which kerosene is sprayed and burned continuously. The tremendous heat released by the combustion of the fuel expands the gases but, as the chambers have open ends (in contrast to the closed cylinder of a piston engine), there is no rise in pressure.

By reason of the rapid expansion, the heated gases force their way at increased velocity through the only exit from the chambers, namely, between the guide vanes in the stator ring of the turbine. These vanes direct the flow to the approximate angle of attack for the blades of the turbine, causing the turbine wheel to rotate at very high speed. In this manner, power is developed to drive the compressor fixed at the front end of the shaft.

After the gases have passed through the turbine they escape through the rear of the unit. This mass of gases being projected rearward at high velocity produces a force that drives the airplane forward.

Although most reciprocating gasoline engines operate on the four-stroke cycle, that is, one cycle is completed in four strokes of the piston or two revolutions of the crankshaft, the outboard motor is an example of a two-stroke-cycle gasoline engine.

As shown in Fig. 11, the same events take place with the exception that they are accomplished in only two strokes of the piston or one revolution of the crankshaft since the piston is not used to expel the exhaust gases and suck in the fresh charge. Instead, while the piston is at the bottom of its stroke, the fresh charge is injected under a slight pressure so that it sweeps out the spent gases. A deflector on top of the piston, as shown in Fig. 11, directs the incoming charge toward the top of the cylinder to do this.

In engines employing the diesel cycle, air alone is drawn into the cylinder and compressed to 500 or more pounds per square inch (psi.). This compression raises the air temperature to the point where, as soon as fuel is injected, combustion occurs, without the help of a spark. The burning takes place at nearly constant pressure.

In the modified diesel cycle, fuel injection is started early enough so that part of the fuel burns at constant volume and the balance at constant pressure.

Engines operating on this modified cycle have compression ratios higher than are customary with the Otto cycle but lower than the usual diesel compression ratios. This necessitates the use of glow plugs, hot bulbs, or similar devices to facilitate starting.

The two-stroke cycle is more suited to the diesel cycle than to the Otto and is thus more widely used in engines employing this cycle. There is no fuel in the intake charge of air, which is used to scavenge the cylinder and thus an excess wastes no fuel. As in all diesels, the fuel is not injected until after the compression of the air.

Gas Turbines.—In its simplest form, a gas turbine power plant consists of: air compressor, combustion chamber, and turbine wheel.

Fig. 11. Events in two-stroke-cycle engine with crankcase scavenging. Left: Down or power stroke; right: up or compression stroke. Intake and exhaust take place at end of power stroke and start of compression stroke. A, intake port to crankcase; B, transfer passage; C, exhaust port; D, spark plug.

The compressor and turbine are mounted as a single rotating unit. After the power plant has been started by an auxiliary power source such as an electric motor or a piston engine, some of the power developed by the turbine is used to drive the compressor. Thus, the output of the turbine engine is the difference between the turbine power and the power required to drive the compressor; it is obvious, therefore, that the efficiency with which the compressor delivers air is of paramount importance.

Two main types of compressors are used on turbine engines: the centrifugal and the axial (as shown in Fig. 10).

The compressed air flows from the compressor to the combustion chamber, where it unites with the fuel, generally kerosene, which is injected through nozzles. A high-voltage spark is used to initiate combustion, after which the spark can be cut off.

The turbine itself consists of a shaft to which are attached the blades against which the high-velocity, high-temperature gases impinge to develop power. Suitability for high-temperature operation is essential for turbine materials. In fact, the major developments that made possible the commercial use of the internal combustion turbine were in metals that retain substantial strength at temperatures of 1200° F. and higher, and in more efficient compressors.

The speed with which the gases pass through the turbine creates special problems of erosion. Also, the materials used must not be prone to "creep" or grow with cyclic variations of temperature (that is, repeated heating and cooling in service).

To achieve higher efficiencies than are possible with the simple gas turbine unit, the three

basic components may be used in multiple and in various arrangements. They are also often augmented by other components such as the regenerator (to recover waste heat and transfer it to a point where the temperature is lower and the pressure higher) and the intercooler (to remove heat from the working medium between stages of compression).

Compared with the reciprocating aircraft engine, the turbine unit has lower specific weight, adaptability to much higher speeds, and the upper limits of thrust capacity of a single unit are much greater. On the other hand, the turbojet version has considerably higher fuel consumption and it is not adaptable to low-speed, light planes. Turboprop units do, however, extend the range of gas turbines to lower-speed applications and have improved fuel consumption. Significantly better fuel economy is also claimed for the turbofan engine.

Compared with the diesel, for example, as applied to locomotives, simple gas turbines use less space, are lighter, and presumably would require less maintenance. Their chief disadvantage is the poorer fuel economy. Also, the output of the gas turbine is more seriously affected by adverse atmospheric conditions of temperature and altitude than is the diesel.

Although further developments may permit favorable comparisons with the steam plant, at present the comparison is unfavorable to the gas turbine. The long-time reliability of the steam plant has not yet been demonstrated by the turbine. The compressors are far larger than the corresponding feedwater pumps. The plant capacity is more sensitive to deterioration of turbine and compressor efficiency. Thus far, the single-unit capacity of the gas turbine is also considerably short of that for large steam turbine installations.

Mechanically the gas turbine unit is quite different from the reciprocating engine. There are no pistons, valves, or ignition apparatus (save for ignition plugs to start combustion of the fuel). After starting, no warming up period is necessary, as bearings are few; there are no metal-to-metal sliding surfaces; consequently, only a simple lubrication system is needed.

Compared with piston engines, turbine units are also:

- (1) Less critical regarding type of fuel. High heat value, not antiknock rating, is the criterion.
- (2) Virtually vibrationless because of the exclusive use of rotating components.
- (3) Self-cooled by airflow, so that no radiator or projecting air scoops are required.

For further information about gas turbines see ENGINE; JET PROPULSION; AERONAUTICS—4. *Flight Propulsion*.

Reciprocating Engines.—Indicator Cards.—The events that occur in any reciprocating engine may conveniently be pictured by a graph with pressure plotted along the vertical distance (ordinate) and actual volume in the combustion space as the horizontal distance (abscissa). These plots are called indicator diagrams or cards.

Various types of indicators have been developed that give an accurate plot of this pressure-volume relationship for an engine in actual operation. For a low-speed engine the mechanism of this indicator can be relatively simple, as shown in Fig. 12.

This device is unsuited for high-speed engines, however, because of the inertia effects of its moving parts and the pencil friction, which

are excessive at high speeds. Other mechanical indicators, as well as optical and electrical indicators, are available that avoid these errors for high-speed work.

Air-Fuel Mixture in Otto Engines.—Theoretically, 15 pounds of air must be mixed with each pound of gasoline in order to supply

Fig. 12. Schematic diagram of indicator for recording cylinder pressure changes in low-speed engine.

just enough oxygen to complete the combustion of the fuel. In actual practice, however, it is seldom that this exact ratio of air to fuel is used. For maximum economy, such as is desired for normal operation, more air must be supplied (usually about 16 to 17 pounds of air per pound of fuel); otherwise combustion will be incomplete and some of the fuel wasted; that is, it will pass through the engine unburned or partially burned.

There are several reasons why this extra air is needed: (1) A thoroughly homogeneous mixture of air and gasoline cannot be obtained in the very short time available, so that all the fuel particles can react with all the oxygen particles. (2) In a multicylinder engine, it is practically impossible to get an absolutely uniform distribution of fuel to all the various cylinders, some cylinders always receive richer mixtures (that is, containing a higher proportion of fuel) than others. (3) The dilution of the mixture by the exhaust products left in the clearance space reduces the probability that all the fuel particles will react with oxygen particles.

When the air/fuel ratio is increased above 16 to 17, the efficiency begins to drop off. When the ratio gets above 18, the mixture becomes so lean that the drop in efficiency and loss of power become quite rapid. Finally a point is reached where combustion does not occur at all.

On the other hand, greater power is obtained (although at the expense of efficiency) with a richer mixture than 15 to 1. Greatest power (such as is needed for quick acceleration and maximum speed up grades) is obtained with air/fuel ratios of 12 to 13.

Thus we see that the setting of the carburetor for maximum power is quite different from that for maximum efficiency. Moreover, for smooth idling of the engine, the mixture must be even richer, 11.2 being a typical figure. This very rich mixture is needed at idling speeds for two reasons: (1) because the pressure in the manifold system is below atmospheric pressure, thus inducing a leakage of air, which dilutes the mixture, and (2) because the amount of fresh mixture entering the cylinder is small, so that there is a relatively large degree of dilution of the charge

by the burned gases remaining in the cylinder.

The modern carburetor is designed to provide approximately these various air/fuel ratios: an economical mixture for the usual operating conditions, richer mixtures when the demand is for greater power, and an especially rich mixture for idling.

Carburetors.—The carburetor is used in engines employing the Otto cycle. Its function is to break up the gasoline into tiny particles and to mix it with the proper amount of air to give efficient combustion.

A simple carburetor of the float type is shown in Fig. 13. Gasoline is forced by the fuel pump into the float chamber shown at the right. The float, so called because it floats in the gasoline, acts to close the fuel intake valve when the gasoline reaches the proper level.

The suction stroke of the engine piston induces a flow of air into the carburetor, as shown at the left. This air passes through a narrowed section called the venturi. The purpose of the venturi is to speed up the flow of air so as to cause a decrease in air pressure to slightly below atmospheric pressure at its narrowest section, known as the throat.

Located at the throat is the jet or discharge nozzle, as shown in Fig. 13. Since the pressure in the float chamber is at atmospheric and that at the jet is slightly below atmospheric, gasoline is pushed through the jet and into the airstream. As the fuel leaves the jet it is atomized or broken up into small drops.

The greater the difference between atmospheric pressure and the pressure at the throat, the more gasoline flows into the air stream. If the jet and venturi are properly proportioned, there is an automatic action that results in greater fuel flow when the airflow becomes greater. When the throttle valve is opened wider, more air as well as more fuel is pulled in, so the proportions (the mixture ratio) remain roughly the same.

Actually, opening the throttle usually increases the speed of the engine, which in turn increases the suction. In the simple carburetor this causes the fuel flow to increase more than the airflow, so that a richer mixture is being supplied to the engine than required. For this reason modern carburetors have automatic compensating devices to maintain the desired mixture proportions at the higher speeds.

In actual practice it is also necessary to provide varied proportions: the richer-than-normal mixture needed for starting the engine, especially when it is cold; the slightly richer-than-normal mixture needed for quick acceleration and for maximum speed up grades.

These changes in mixture ratio are also effected automatically in carburetors built today. For example, at least two jets or fuel passages are provided from the float chamber to the venturi, one for idling and low-speed operation, the other for higher speeds or harder pulling. There are also various other auxiliary devices built into the carburetor, mostly to change the fuel/air ratio or to take care of some special condition.

One of these devices is the choke valve. It looks much like the throttle valve but it is located in the air intake passage of the carburetor. When it is partly closed, a high vacuum is formed beneath it. More fuel and less air are pulled in, giving the much richer mixture needed to start the engine. On most modern cars the choke

valve is controlled automatically; that is, the driver has no control over it.

The simple carburetor shown in Fig. 13 is of the updraft type; that is, the air enters the carburetor at the bottom and leaves it at the top. Today, on most vehicles at least, carburetors are of the downdraft type—the air enters at the top and leaves at the bottom.

The downdraft carburetor permits a manifold of larger cross section because the fuel flows down into the manifold instead of being lifted up into it. The location of the carburetor above the engine makes it more accessible for inspection, adjustment, and repair, and the air entering the carburetor is cooler.

Fuel Injection.—The heart of the diesel engine is its fuel injection system. Its purpose is to force a small amount of fuel (broken up

Fig. 13. Carburetor in its simplest form.

into finely divided particles) into the highly compressed, high-temperature air in the cylinder just before the piston reaches the top of its compression stroke.

There are two methods of injecting fuel into the combustion chamber: air injection and airless injection (also called mechanical injection and solid injection).

With air injection, the fuel is sprayed into the cylinder by means of highly compressed air. This method is little used, however, because it requires a compressor, which adds mechanical complexity and weight and consumes up to 10 per cent of the brake horsepower.

Today, therefore, the airless injection method predominates. There are many variations of this type, such as the unit pump injection system (Fig. 14) and the common-rail system.

In any solid injection system, it is necessary to have a pump that will force the fuel into the cylinder against the compression pressure of 500 to 600 psi. The volume of liquid to be injected is very small, and it must be injected at a very high velocity in order that it may be thoroughly atomized and yet be capable of penetrating through the whole volume of air. The jet must be so disposed and directed that a stream of liquid is not likely to impinge on the cylinder wall or piston, where rapid carbonization would occur.

With the unit injector, the pump and nozzle are combined in one unit, the whole mechanism being fitted in the cylinder head. It is operated by a rocker arm controlled by the same camshaft that operates the valves. The pump itself consists of a plunger fitting closely in a cylinder. There

are also means for varying the amount of fuel it pumps in one stroke. The plunger builds up pressure on the small amount of liquid in the cylinder until the pressure is great enough to open

Fig. 14. Diagram of diesel fuel pump and injection nozzle.

a spring-loaded check valve. This may be as high as 20,000 psi. When it opens, the fuel is forced into the cylinder through a number of very small holes in the nozzle, shooting a fine spray in all directions.

Controlling the amount of fuel pumped by the injectors speeds up or slows down the engine, just as does opening or closing the throttle of a gasoline engine.

In the common-rail system, a constant pressure is maintained in the fuel discharge line, and the discharge to the cylinder is controlled by the lift, timing, and duration of opening of the fuel valve. One or more pumps are used to furnish fuel under high pressure to one pipe or reservoir having branches to all the cylinders.

Fuel injection has also been investigated for gasoline engines—both aircraft and automotive—and a few systems are being used. They are not more popular because they are much more complicated and expensive than carburetors, and improve power and economy only slightly. (See also FUEL INJECTION.)

Combustion Chambers.—The combustion chamber is the space at the head end of the engine where burning of the fuel occurs. In the diesel engine, since the fuel is injected after the air has entered the chamber, it is also the space where the fuel and air are mixed before and during the burning.

The combustion chamber must be designed most carefully since upon it depends in large measure how well combustion occurs, that is, how quickly, how completely, how smoothly, and whether with or without knocking.

In general, combustion chambers of four-stroke spark-ignition engines are classified according to valve arrangement and the degree of turbulence that is induced in the chamber during the burning process.

Common types of nonturbulent chambers include the T-head, L-head, F-head, valve-in-head, and domed-head designs (see Fig. 15).

The T-head is practically obsolete because it does not permit the use of high compression ratios and requires two camshafts.

Fig. 15. Combustion-chamber shapes, valve locations, and possible spark-plug locations (P).

The L-head design, long used in the automotive field, has a more compact combustion chamber, permitting higher compression ratios, and requires only one camshaft; it is, however, restricted in valve size by the center-to-center distance between cylinders in a multicylinder engine.

The F-head permits large valves, requires one rocker arm mechanism for the inlet valve, has a slightly more compact combustion chamber, and permits a slightly higher compression ratio than the L-head design.

The valve-in-head design has a very compact combustion chamber, but it is restricted in valve size. It permits higher compression ratios than the foregoing designs, but it requires either rocker arms and pushrods or an overhead camshaft mechanism.

The domed-head is a modification of the valve-in-head design that permits large valves, has the most compact combustion chamber, and permits the highest compression ratio. It requires an overhead camshaft or otherwise complicated valve mechanism for cylinder in-line engines. Similar to this design is the wedge-shaped combustion chamber used by Chrysler Corporation in their Slant-6, die-cast aluminum engine (see Fig. 6).

Fig. 16. Turbulence type of combustion chamber developed by Sir Harry Ricardo.

Sir Harry Ricardo, an English engineer, introduced high turbulence into combustion-chamber design by lowering part of the cylinder head (see Fig. 16) so that the piston closely approaches this

part at the top of its stroke. The charge is forced out of this thin space, greatly agitating the entire mixture and resulting in a faster, more complete combustion.

Most four-stroke-cycle compression-ignition engines have valve-in-head construction. The classification of these engines according to combustion-chamber design is based upon the method of controlling the combustion process, such as the open combustion chamber and the precombustion chamber. In the open combustion chamber

Fig. 17. Allis-Chalmers open-chamber, four-stroke diesel engine is rated at 340 bhp. (max.) at 1,800 rpm. It is used on boats, tractors, and industrial machinery.

the fuel is injected under high pressure directly into the clearance space or chamber between the piston and the cylinder head (see Fig. 17).

The piston head is usually shaped to fit the fuel spray, and air swirl moves the unsprayed

Fig. 18. Main combustion chamber and precombustion chamber of Mercedes-Benz diesel engine.

air into the fuel spray. Air swirl is accomplished by intake port design, by shrouding the intake valve, or in the two-stroke engine, by using tangential intake ports. The open chamber

gives highest efficiency and easiest cold starting with the lowest compression pressure.

The precombustion chamber is a small chamber located in the cylinder head and connected by a small passageway to the main part, in the cylinder (Fig. 18). The prechamber holds 30 per cent or less of the total combustion air. The fuel is injected into the small chamber, and except under light loads, partial combustion occurs and discharges the burning mixture into the main combustion space, creating turbulence, mixing the fuel and air, and producing vigorous burning. This type of combustion chamber produces a smooth combustion process, but it has fairly high fluid friction and heat transfer losses.

Ignition.—The type of ignition used on compression ignition engines depends on the degree of compression reached, as follows:

(1) Low-compression engines (6 to 10 compression ratio) require some external heat application to a tube, bulb, or plate, at least for starting (called surface ignition). After operating temperatures have been reached, a sufficiently high temperature is maintained at the tube, bulb, or plate to ignite the fuel.

(2) Medium-compression engines (10 to 14 compression ratio) require some form of ignition, such as an electric spark or electric hot wire, for starting. The spark is sometimes still used even after operating temperatures have been reached.

(3) The high-compression engine (14 to 16 compression ratio) is the true diesel. It uses a compression pressure of about 500 psi. It requires no means other than compression for igniting the fuel.

In the gasoline engine it is necessary to supply a spark to start the burning of the fuel-air mixture after it has been compressed by the upward stroke of the piston.

A spark plug (or sometimes two of them) fits into the wall of the combustion chamber. It has two wires or electrodes, which extend slightly into the chamber and are separated from each other by a narrow gap. High-voltage electricity is led to the spark plug so that it jumps the gap from one electrode to the other at the proper instant. This causes a spark, which starts combustion. Either a battery system or a magneto system may be used to supply the electricity to produce the spark.

A typical battery ignition system is shown diagrammatically in Fig. 19.

Fig. 19. Simplified battery ignition circuit diagram.

There are two circuits in the electrical system, that is, two complete paths around which the electricity flows. These are the primary or low-voltage circuit and the secondary or high-voltage circuit.

The low-voltage circuit (12 volts on passenger cars) is as follows: the current flows from the battery (one terminal of which is grounded to a metal part of the car) through the ammeter, ignition switch, the heavy or primary winding of the coil (several hundred turns of wire of comparatively large diameter) to the ignition points of the breaker. Here the circuit is completed by grounding. A condenser is also attached to the primary circuit, the other end being grounded.

The secondary circuit starts from ground in the secondary winding of the coil (which consists of 10,000 to 20,000 windings of fine wire) and passes through a heavily insulated wire into the center of the distributor cap. A contact carries the current to the rotor, which, as it revolves, distributes the current to the six segments (as shown in Fig. 19), which in turn send it to the spark plugs through the connecting wires. (About 10,000 volts is needed to make a spark jump a gap of 0.025 to 0.040 inch in an engine in operation.) After the current jumps the spark-plug gap, igniting the fuel mixture, it is grounded.

As long as an electric circuit is flowing steadily in the primary circuit, no current flows in the secondary. If that circuit is suddenly broken, however, a momentary high voltage is set up in the secondary circuit. This may be as much as 20,000 volts.

This operation is accomplished by means of the breaker in the primary circuit, which cuts this circuit often enough to send a high voltage to each spark plug each time it needs to be fired. It consists of a pair of contacts, which are opened and closed rapidly by a cam having as many points as there are cylinders. The cam is operated by the engine so that the contacts open near the top of the compression stroke of each piston. Thus, the primary circuit is continually being broken, thereby sending a series of high-voltage surges through the secondary circuit of the system.

A condenser is incorporated in the breaker case to help give a quick, clean electrical break and to get a good spark in the combustion chamber.

The function of the distributor is to get the high-voltage current generated in the secondary coil to the proper spark plug at the proper time.

A magneto ignition system has all the parts of the battery ignition system and, in addition, a generator for producing alternating current impulses directly in the primary winding of what is, in effect, a spark coil.

An advantage of the magneto is its self-contained character. All of the elements of the system are in one compact unit from which it is necessary only to run a low-voltage cable to the ignition switch on the dash, and high-voltage cables to the spark plugs.

Two electrical developments that look promising are transistorized ignition and the alternator for cars.

The successful application of the transistor as a solid electronics switch to ignition systems was announced by Electric Autolite in 1959. It is based on the transistor's ability to amplify current. It provides increased life for ignition contacts and improved output voltage. The system is being extensively field tested prior to its anticipated introduction into production vehicles.

The alternator was first offered by Chrysler

in 1960. Compared with the d-c generator, it is lighter, has longer life, and gives improved performance.

Compression Ratio.—When the piston is as close to the top of the cylinder as possible, that is, at top dead center, the small volume (which is the combustion space) is called the clearance volume. The volume of cylinder that the piston moves through is called the displacement. It depends on the bore (that is, the diameter of the cylinder) and the stroke (or the distance through which the piston moves). The compression ratio is defined as the piston displacement plus the clearance volume (which is the total volume when the piston is at bottom dead center) divided by the clearance volume. Higher compression ratios, within limits, result in increased thermal efficiency, which in turn provides improved engine performance. Thus, the higher horsepower of modern engines is due, in part, to their higher compression ratios.

At a particular compression ratio, the ideal Otto cycle is more efficient than the diesel. In actual practice, however, diesel engines are generally more efficient than Otto-cycle engines because the former can operate at higher compression ratios. If the compression ratio is too high (for a particular fuel) in an Otto engine, a phenomenon called detonation or knock will occur.

Detonation.—Briefly, detonation may be explained as follows: When the mixture is ignited, combustion starts at the spark and spreads through the combustion chamber behind what is called the flame front. As the temperature of the burned gases rises, they expand and compress the unburned gases. If the compression ratio of the engine is too high, the unburned gases are compressed to the point where they get so hot that spontaneous combustion begins at some point remote from the spark. There is a rapid increase in pressure at this point, which results in violent, vibrating pressure waves. The audible evidence is a metallic click or knock when these waves strike the wall of the combustion chamber. Excessive detonation is accompanied by severe pressures, which may eventually damage the engine. In addition there is a small loss of power when detonation occurs. However, since the engine is operating at close to maximum thermal efficiency when detonation is incipient, maximum efficiency is often obtained when there is a slight detonation or "ping."

It should be noted that compression ratio is not the sole determining factor affecting detonation. For this reason, such developments as the following have permitted compression ratios to be increased without detonation.

(1) Special substances (called antiknock agents), that can be added to a fuel to help it to resist detonation. These include tetraethyl lead, tetramethyl lead, and triptane.

(2) Redesign of the shape of the combustion chamber to reduce detonation.

(3) Increasing the rate at which heat is carried away from the combustion space by the use of thinner sections in the head, by the use of materials of higher heat conductivity, such as aluminum alloy and bronze for the head, and by improving the conductance of heat from the top of the piston.

(4) Reducing the number of local hot spots in the combustion space by better finishing, which removes small projections that may become red hot and cause spontaneous ignition, and by more efficient cooling of various parts near or in the combustion chamber, such as the spark plug and the valve seats.

Octane Rating.—The antiknock properties of gasoline are measured by a concept called oc-

tane number; the higher the octane number, the less the tendency of a gasoline to knock. The octane rating of a fuel is obtained by supplying the fuel to a standard test engine and comparing its knocking property with that of a reference fuel of known octane number. The reference fuel is a mixture of isooctane (which has high antiknock properties) and heptane (which has very poor antiknock qualities). If a fuel being tested has the same knocking characteristics as, for example, a mixture of 70 per cent isooctane and 30 per cent heptane, it is said to have an octane number of 70. By this method of rating, pure isooctane would have a rating of 100.

Fuels have been developed with better knocking properties than isooctane and therefore with antiknock ratings of greater than 100. These fuels, which are particularly for aircraft use, are rated by a system called performance number. For example, the performance number of triptane plus 4 cc. tetraethyl lead per gallon is 360. This means that in a supercharged engine it is capable of giving 3.6 times as much power as isooctane.

Cetane Number.—Analogous to octane number for gasoline is the cetane number of fuel oils. This number is a measure of the speed with which the fuel ignites, that is, the time lag between the beginning of injection and the rapid pressure rise due to combustion. If the cetane number of a fuel is too low for a particular engine, rough running will result, especially at high speeds. Fuels of high cetane number give smooth combustion and provide easy starting. The lower the engine speed, the less important the cetane number.

Cetane is a fuel with a high ignitability. It is mixed with alpha-methylnaphthalene, which has a low ignitability, to form a reference fuel. If the fuel being tested has the same ignitability (measured by the ignition lag) as a mixture of, for example, 60 per cent cetane and 40 per cent alpha-methylnaphthalene, it is said to have a cetane number of 60.

In general, cetane numbers of fuel oils range from 30 for large, slow diesel engines to as high as 60 for high-speed engines.

Corresponding to antiknock agents for gasoline there are certain ignition accelerators that may be added to diesel fuels in the proportions of 1 to 5 per cent. These substances, such as ethyl nitrate and amyl nitrate, reduce the delay period and so tend to reduce "diesel knock." Unfortunately, they also add to the cost.

Supercharging.—Supercharging is often used to retain the sea-level power (or as close to it as practicable) of piston engines operating at altitude. It is also used, in certain cases, to increase the output of land and marine engines, especially diesels.

Quite simply, supercharging is a method of increasing the density of the air supplied to the engine by some sort of compressor. In other words, by compressing the air to a density greater than atmospheric, we are able to get more of it into the cylinders, thus providing greater power without increasing the size of the engine and without having to run it at undesirably high speeds.

The supercharger consists of an air compressor and some means of driving it. The compressor may be of any type—reciprocating, rotary, positive displacement, centrifugal, or axial flow.

Supercharging is particularly important for aircraft piston engines because (1) at high al-

titudes the power of an unsupercharged engine falls off drastically (for example, an unsupercharged engine of 1,000 hp. at sea level would produce only 500 hp. at 18,000 feet), and (2) it is possible to produce a marked improvement in sea-level performance of an engine without seriously affecting its life or dependability.

Usually, exhaust-driven centrifugal units, called turbochargers, are used because they utilize part of the exhaust energy, which would otherwise be wasted.

Except for high-speed engines, such as are used on racing cars, supercharging is not common on automobiles because, if the engine is already operating at optimum compression ratio with the available fuel, the addition of supercharging would cause detonation. To eliminate the detonation it would be necessary to lower the compression ratio, enrich the mixture, or increase the octane number of the fuel.

Supercharging has entirely different aspects when applied to diesel engines, where it tends to suppress rather than promote knock. For this reason, supercharging of diesels is much more common.

Probably the most used methods of supercharging diesels are by means of the Roots-type blower and the turbocharger.

The Roots blower (Fig. 20) consists of two rotors inside a housing. Each rotor has two, three, or four lobes, which fit together like gear teeth as the two rotors are driven from the engine crankshaft. Air is drawn in and carried around the outer side of the rotors to the outlet and into an air chamber which entirely surrounds the lower part of the cylinders. This compartment of air under pressure is fed to the cylinders.

Although these blowers are somewhat expensive to build, they have been very popular because they give trouble-free service for long periods and, except for a characteristic whine at highest speeds, are quiet running.

Fig. 20. Roots blower.

The turbocharger (Fig. 21) is inexpensive and requires no attention beyond bearing lubrication. As with the aircraft type, an exhaust gas-driven turbine drives the compressor that supplies the air to the engine.

Valves and Mechanism.—In the operation of the internal combustion engine a fresh charge of air, or mixture of fuel and air (depending on whether it is a diesel or Otto engine), must flow into, and be trapped in, the cylinder at the proper

time during each cycle. A short time later the products of combustion must be allowed to flow out of the cylinder. On two-stroke engines, this is frequently accomplished with ports (see Fig. 11), but on four-stroke engines, and also on many two-stroke units, valves are used.

Fig. 21. Scania-Vabis six-cylinder diesel engine with turbocharger.

The first requisite of valves is that they allow the engine to breathe freely, that is, the resistance to flow through the valve opening should be minimum so that there is little difference in pressure between the cylinder and the surrounding atmosphere. When the valves are closed they must seal the combustion space tightly, or loss of compression will result.

The mechanism must open and close the valve at the proper times as well as giving it the desired lift. The demand for quiet operation has brought forth designs that seat the valves with practically no noise.

The most common valve is the poppet, which consists of a head and stem. The head was originally a flat disk to which the stem was attached. A more modern version is the tulip valve, which makes possible good streamlining of the head into the stem without adding excessive weight. Hollow valve stems are used to reduce weight. The hollow stem is sometimes filled with sodium (which melts at valve-stem temperatures and is an excellent conductor) so that it carries the heat from the head along the valve stem.

Sleeve Valves.—The double-sleeve valve was invented by Charles Y. Knight in 1905. He applied it to an engine that was called the "silent Knight" because its operation was so quiet, due to the reduction in valve noises. Chief disadvantage was the difficulty in providing satisfactory lubrication. Failures in lubrication occasionally caused the sleeves to stick, which often wrecked the engine.

The valve consists of two concentric sleeves (Fig. 22) located between the piston and the cylinder wall. The sleeves are driven by an eccentric shaft operated at half speed. Ports in the two sleeves and in the cylinder wall form the intake and exhaust openings. The upper ends of the sleeves slide back and forth between the cylinder head and the wall.

In 1910 Peter Burt patented a single-sleeve-valve engine. He was able to use a single-sleeve valve to open and close both intake and exhaust ports by giving it a combination of two motions, that of vertical reciprocating and angular oscillation.

Fig. 22. Section through cylinder and sleeves of Willlys-Knight engine.

Manifolds.—**Intake.**—The intake manifold provides the passage for the air and fuel mixture (or air alone, in the case of the diesel) to travel to the intake ports or valves of the cylinders.

An ideal manifold for a gasoline engine would supply an equal charge of identical fuel/air ratio to all the cylinders at all speeds, loads, and rates of acceleration.

In actual practice, something less than this is attained, for various reasons. For one thing, less than half the gasoline is actually vaporized by the carburetor, the rest being in the form of fuel particles ranging from a fine mist to particles of appreciable size. Thus, a manifold that distributes the air equally among the various cylinders will not necessarily distribute the fuel equally, for the inertia effect of the fuel particles is considerably greater than that of air molecules.

To get the fuel properly vaporized, heat from the exhaust gases is supplied by one of the following methods:

- (1) By preheating the air before it enters the carburetor.
- (2) By surrounding the "T" of the manifold with an exhaust jacket.
- (3) By heating that portion of its wall where any unvaporized fuel collects.

The first method was used for a good many years, but it has now been discarded in favor of the other two, which have a less detrimental effect on engine power.

A thermostat is generally used to shut off the heat automatically when the engine warms up.

Exhaust.—The exhaust manifold collects the gases from the exhaust openings of the various cylinders and conducts them to a central exhaust passage. It is designed to avoid as much as possible the overlapping of exhaust strokes. This is often done by dividing the manifold into two or more branches so that no two cylinders will

exhaust into the same branch at the same time.

Cooling.—All internal combustion engines require some means of cooling. Very roughly, one third of the energy of the fuel is transformed into mechanical energy and one third is removed with the exhaust gases. The remaining third must be transferred through the cylinder walls and head and carried off by some cooling medium circulating over the exterior surfaces.

Air cooling has been most popular in the aircraft and motorcycle fields. It was much used when the automobile industry was in its infancy, but then it lost its popularity. For many years, no American car was air cooled, although a number of European ones were—a notable example being the Volkswagen engine. Then Chevrolet reintroduced the idea in America with its 1960 Corvair.

When air is used as the coolant, the outer surfaces of the cylinders and heads are cast with fins and flanges to give more heat-dissipating surface (see Fig. 5).

With liquid cooling, the cylinders and heads are jacketed by casting them with cored passages through which the cooling liquid is circulated.

The circulation of the liquid may be by thermosiphon effort or pump.

The thermosiphon principle, used only on a few tractors and road vehicles, depends on the fact that heated water expands and therefore tends to rise. The cooling system is so arranged that this tendency is used to effect the circulation of the water through the system.

Generally, the circulation of the cooling water or other liquid is accomplished in more positive fashion by means of a small centrifugal pump.

For stationary and marine applications where an abundance of cooling water is available, the heated water is wasted and replaced by cold water. On vehicles and liquid-cooled aircraft engines, however, the water is used repeatedly, being cooled between its courses through the jackets in an air-cooled radiator that forms part of the cooling system.

In addition to a pump, most modern liquid-cooled systems employ a thermostat, which prevents the water in the engine jacket from circulating through the radiator until its temperature has reached a point suitable for efficient engine operation.

Because the temperature of a cooling system open to the atmosphere is limited by the boiling point of its liquid (212° F. for water and considerably lower if an alcohol is used as the antifreeze), pressure systems have been devised. A special pressure cap, designed to relieve the pressure when it reaches the value for which it has been set, must be used. It must also relieve the vacuum that forms in the system when the steam therein condenses after the engine has been shut down.

Evaporative cooling systems employing a hopper are often used on small stationary engines. The hopper is a large open water tank to which make-up water is added as evaporation takes place. Other evaporative systems employ a radiator, which is not open to the atmosphere, but becomes a condenser of steam. The condensate can then be pumped into the water jacket.

Lubrication.—The distribution of oil to the bearings in an engine can be accomplished in several ways. In early engines, and even now in some stationary engines, oil is fed to each bearing from an individual supply. Usually a

gravity sight-feed oiler is used for each cylinder, main bearing, and crankpin bearing, which makes use of a "wiper" action to get the oil from the oiler outlet.

Next came the mechanical oiler, which delivers the oil under pressure from a common supply to each bearing by means of individual plungers and oil lines. The quantity for each bearing is metered according to the need for lubricant. Some bearings on large stationary engines are oiled with ring oilers, which dip into a small sump and carry the oil up to the shaft.

The automotive engine usually has a self-contained oiling system in which the oil is continuously recirculated. The lower part of the crankcase provides the sump or reservoir for the oil supply. There are several systems for supplying the oil to the moving surfaces.

In the splash system the lower ends of the connecting rods have dippers, which travel through oil troughs at the bottom of the stroke and splash the oil over the lower cylinder surfaces as well as the crankcase surfaces. The piston spreads the oil over the upper cylinder surfaces while ducts or channels lead the oil to the crankshaft and camshaft bearings. The lower connecting-rod bearings have oil forced in through an oil hole in the lower half during the time the rod dips into the oil. The main disadvantage of this system is the lack of positive circulation to the bearings, which limits the bearing loading and quantity of oil circulated. Also, the bearings are not cooled appreciably by the oil.

Actually, the splash system is almost nonexistent today, having been replaced by the fully pressurized oil system. Frequently, it is also equipped with full-flow oil filters as shown in Fig. 23.

Airplane engines must operate satisfactorily in any position. For this reason they generally use what is called the dry-sump system. That is, very little oil is retained in the crankcase sump. The oil is scavenged by a pump and delivered to a main oil tank placed in any convenient position. This necessitates the use of at least two pumps: one for scavenging the crankcase and the other for feeding the oil back to the main bearings and other parts of the engine.

There are three ways in which oil can be consumed in an engine in good condition:

- (1) Burned in the combustion chamber.
- (2) Leakage where the crankshaft or other shafts protrude from the crankcase.
- (3) Loss of oil mist or vapor from the breather.

Engine speed is the most important factor affecting oil consumption. As engine speed increases the oil temperature rises, reducing the oil viscosity. This causes more oil to flow through the crankpin bearings, which in turn causes more oil to be sprayed on the cylinder walls. At high speeds the rings do not follow the cylinder wall as closely as at low speeds. They tend to act something like surfboards, riding on the film of oil. Under this condition more oil is passed to the combustion chamber instead of being scraped back into the crankcase.

Higher speeds also cause more wear of moving parts, which then have larger clearances for oil to flow out.

In general, the condition of the cylinder bores, pistons, rings, and the various clearances between these parts have more to do with oil consumption than do the characteristics of the lubricant used.

The development of oil control rings has done more to control the oil passed to the combustion chamber than any other factor. However, a good oil control ring that gives satisfactory oil consumption at high speeds is apt to cause insufficient lubrication and excessive wear at low speeds. The best compromise seems to be excessive oil consumption at high speeds.

Fig. 23. Lubricating system for Chrysler Corporation V-8 engine. The oil pump draws the oil from the sump through a fixed screen suction pipe and forces it through the full-flow oil filter. From there it flows to the various parts of the engine.

In some small two-stroke engines, as used in marine service, the lubricating oil is mixed with the fuel and fed directly to the cylinder walls where the gasoline evaporates from it into the combustion space.

Engine Vibration and Mechanical Balance.—In general, there are two forms of motion in a reciprocating engine that may give rise to vibration: rotary and reciprocating. Mechanical balance of an engine is attained when the moving parts (both rotating and reciprocating) are arranged so that they counterbalance in operation, thereby minimizing vibration.

Rotating parts are balanced mechanically by bringing them into static and dynamic balance. A rotating part is in static balance if, when its bearing sections are placed on parallel knife edges, set in a horizontal plane, the part remains in any position to which it is rotated. Such a part is not necessarily in running or dynamic balance. That is, it is possible to have the center of gravity of the part lie on its axis of rotation (thus giving static balance) and still not have the weight balanced along the axis, so that the part wobbles endwise when it is rotated at high speed. The crankshaft and flywheel are the principal rotating parts to be balanced mechanically.

Bringing the reciprocating parts into mechanical balance is much more complicated than for rotating parts. The weight of the piston and connecting rods moving one way and then the other produces considerable vibration. The crankshaft is subject to shocks in bringing these parts to a stop at each end of each stroke. These shocks are called "primary inertia forces." They are increased in intensity by the gas pressure on the piston at the end of the cycle.

In a well-built engine, all pistons and all connecting rods are the same weight within close limits, and the flywheel and crankshaft assembly is balanced dynamically. By such practices much of the vibration is minimized.

There are, however, certain types of vibration that still must be eliminated or at least minimized in every engine. For instance, there is torsional vibration of the crankshaft, which is caused by a slight winding and unwinding of the crankshaft resulting from the application and release of the power impulses on the crank throws of the crankshaft.

A number of methods are used to minimize torsional vibration. One is to design the crankshaft so that its basic or highest critical speed is above the maximum speed of the engine, and to damp out the torsional vibration that occurs at lower speeds by special means or by natural bearing friction. Most six- and eight-cylinder automotive engines depend on torsional vibration dampers because of the relatively long crankshafts and high speeds of these engines. One type, called a "harmonic balancer," is provided with an inertial weight that is set in motion by the torsional vibration but, because its motion is out of phase with or opposed to that of the crankshaft, it tends to neutralize the vibration of the crankshaft or damp it out.

Power and Its Measurement.—Engines of all kinds are rated in horsepower, which is a measure of the rate at which they can work. The term horsepower is used in different ways, for instance: (1) Indicated horsepower is the power developed inside the cylinder by the expansion of the gases. It can be obtained by measuring the area of the indicator card. (2) Brake horsepower is the power the engine actually delivers. It can be measured by means of such equipment as the Prony brake, fluid friction dynamometer, electrical dynamometer, and the transmission dynamometer.

The difference between the indicated horsepower and the brake horsepower is called the friction horsepower. It represents the horsepower lost because of the friction of the moving parts.

There is another commonly used—if more or less fictitious—horsepower called the AMA rating (known in England as the RAC rating and often erroneously called the SAE horsepower). For years it was widely used for taxation purposes, although the practice is dying out. The formula for calculating this horsepower is $D^2N/2.5$, where D is the diameter or bore of the cylinder in inches and N is the number of cylinders. This simplified formula is based on three assumptions: (1) a mean effective pressure of 90 psi.; (2) a mechanical efficiency of 75 per cent; (3) a piston speed of 1,000 feet per minute.

At the time when the Royal Automobile Club of England developed this formula, it represented fair average values for automobile engines, but in modern engines they are very much exceeded. As a result, a good modern engine may actually develop a brake horsepower of three or more times its AMA rating.

Efficiencies and Their Measurement.—The engineer uses various types of efficiency to describe how well his engine is operating. For instance, he uses the expression "thermal efficiency," which is simply output divided by input. If the output is the net work as obtained from an indicator diagram and the input is the energy contained in the fuel, the ratio is the indicated thermal efficiency. If the output is the brake work, as measured, for example, by a Prony brake, then the brake thermal efficiency is obtained.

Also of great importance is the mechanical

efficiency, which is the brake horsepower divided by the indicated horsepower.

Friction horsepower is determined by driving the engine with the dynamometer and noting the consumption of power. Thus, this power includes that necessary to pump the gases into and out of the cylinders. It goes up rapidly at high speeds. At maximum speed, it may be about half the brake output of the engine.

It is to be noted that mechanical efficiency drops off as speed increases. This is due to the rise in friction horsepower at the higher speeds.

Since the fuel consumption is related directly to the brake thermal efficiency, as the curve for brake thermal efficiency rises the fuel consumption decreases. Over a fairly wide range both these curves should vary little. At very high speeds, however, the brake thermal efficiency drops off rapidly, causing the fuel consumption to rise steeply. Thus, not only does the power necessary to drive a car at high speeds increase very rapidly (about as the cube of the speed), but the efficiency of the engine falls off.

Torque is significant for an automobile engine because the acceleration or pickup of the car depends on the available torque, which is the maximum possible torque at a given speed minus the torque being developed to maintain the speed constant. A high torque at low speeds indicates ability to pick up a heavy starting load.

Mean effective pressure (often abbreviated to mep.) is the average net pressure acting on the piston for the stroke that does the same work as represented by the indicator card. It measures the relative power per cubic inch of displacement. The higher the mep., the greater are the power and work obtained from a cylinder of a given size; therefore, for economy in the use of materials, the mep. should be high. The indicated mep. can be determined by measuring the area of an actual indicator card. The brake mep. at any speed can be obtained from the formula:

$$\text{Brake mep.} = \frac{792,000 \times \text{bhp.}}{D \times N}$$

where:

bhp. = brake horsepower of the engine at N
 D = piston displacement, cubic inches
 N = engine speed, rpm.

Gas Engines.—There are two general types of gases used as the fuel in gas engines:

- (1) Those that become liquid with the application of only a moderate degree of pressure.
- (2) Those that remain gases until compressed under very high pressures at very low temperatures.

The first classification includes such fuels as propane and butane, which are designated liquefied petroleum gases (LPG).

LPG is used to some extent as a fuel for trucks and buses. If it is used in engines designed to burn gasoline, certain changes must be made, such as the use of a pressurized fuel tank, the addition of a converter (which is a combination pressure regulator and vaporizer), and a special carburetor.

The use of LPG as a fuel for automotive vehicles is limited, however, by several factors, such as the high degree of explosiveness of the fuel (it is more easily exploded than gasoline), the need for engines of high compression ratio to take advantage of the high antiknock rating of the fuel, and its relatively high cost.

Purely gaseous fuels are used only in sta-

tionary engines because the engine must be near its fuel source. It is impossible to carry even highly compressed gases in a quantity great enough to permit any considerable range of action to a vehicle.

Gas is used as a fuel only when there are available cheap natural or byproduct gases in adequate quantities. Thus, outside the natural-gas regions, the most extensive application is in connection with blast furnace plants, in which large quantities of combustible gases are produced as a byproduct. Here they can be used to operate blowing engines that furnish air to the furnaces and to drive generators to supply electricity for the plant and neighboring communities.

Most gas engines operate on the Otto cycle, although dual-fuel engines have also been built that operate on the diesel cycle and run on either gas or fuel oil. Another variation is the gas-diesel engine in which a small quantity of fuel oil is introduced at the same time as the gas is injected into the cylinder.

INTERNAL REVENUE, în-tîr'năl rěv'-ě-nŭ, a system of domestic taxation by national governments. Since the beginning of the 20th century, it has accounted for the largest share of national governmental revenues in the major economies of the world. In Great Britain and many present or former British dominions—such as South Africa, Australia, and New Zealand—the system is called inland revenue. In the United States, Canada, and most of Europe, internal revenue is the term. The basic composition is the same under either name, although individual taxes vary in name and importance from nation to nation.

Internal revenue is distinguished from customs on the one hand, and from "miscellaneous receipts" on the other. Customs or duties are ad valorem taxes levied on foreign trade, almost always on imports. "Miscellaneous" or "other receipts" represent a catchall group of revenue sources, ranging from the sale of public lands to the income of government-owned corporations.

Internal revenue (or inland revenue), then, consists of the system of taxes levied by the national or federal government on trade, property, and income existing within the national boundaries. State and local revenues are not included in the concept of internal revenue. Taxes levied by state and local governments are internal to the national economy. Since the states levy no customs duties, there is no necessity to distinguish their internal revenue.

Historical Background.—Internal revenue taxes, particularly property taxes, are as old as recorded financial history. Until the commercial revolution of the 13th and 14th centuries, however, foreign trade did not produce a very substantial share of national revenues. The development of international trade, particularly in western Europe and the Near East, changed all this. At the same time, then-current economic and political philosophy dictated the emergence of

protectionism. Customs duties were imposed partly to discourage the importation of foreign goods, and partly to raise revenues. As has happened so often with sumptuary taxes, customs duties failed to discourage international trade to any substantial extent, but they did raise revenues. The discouragement was so slight, in fact, that by the 18th century customs duties provided the bulk of national revenues in the Western World.

Great Britain.—In Great Britain in the 18th century, the principal sources of inland revenue were excise and stamp taxes. By 1800, death duties in the form of stamps required for documents and of estate taxes, had been incorporated into the inland revenue system, along with income taxes. The formal organization of the system occurred in 1849, when the Board of Inland Revenue was created. The board has unified jurisdiction over excises, stamps, death duties, and income and profits taxes.

The organization of the inland revenue system coincided with the decrease in importance of customs duties. Great Britain became formally and completely committed to free trade in 1860. At that time, a tradition of relatively heavy "outlay" or excise taxes on a limited group of commodities was established. That tradition has been carried through to the post-World War II period. Land and real estate taxes are part of the "local rate" and therefore excluded from the inland revenue total. The largest single share of the British inland revenue has been produced by income and profits taxes since 1930, but such taxes have not assumed the same relative importance as income taxes in the United States.

United States.—The internal revenue system of the United States has been under the jurisdiction of the Treasury Department since its inception in 1789. During the early years of the republic, however, internal revenue accounted for a very small percentage of total federal revenues indeed. As in Great Britain, the overwhelming majority of revenues came from customs duties. The accompanying table shows that internal revenue did not pass customs duties as a source of federal revenue until the beginning of the 20th century. Emergency taxation during and immediately following the Civil War raised internal revenue above customs receipts in the 1861-1870 period but this was a temporary condition stemming from war financing.

UNITED STATES GOVERNMENT RECEIPTS
Selected Years 1800-1960
(millions of dollars)

Year	Customs	Internal revenue	Other revenue	Total
1800	5.0	0.4	0.3	5.7
1825	16.4	1.5	2.1	21.0
1850	25.6	¹	2.9	28.5
1875	186.2	120.0	30.6	336.8
1900	185.1	206.6	43.2	434.9
1925	464.0	3,163.7	679.0	4,306.7
1950	431.7	40,259.8	3,094.4	43,785.9
1960	1,104.9	76,658.2	17,367.1	95,078.2

The first internal revenue taxes levied in the new United States included an excise tax on whiskey and other domestic distilled spirits, and an excise tax on carriages. The liquor tax created a considerable amount of indignation, particularly among the rum distillers of Massa-

chusetts and the whiskey producers in the Allegheny and Cumberland mountain regions. The indignation culminated in 1791 in the Whiskey Rebellion (q.v.) which was not quelled until 1794.

The carriage tax in turn led to the Supreme Court case of *Hylton v. United States* (3 Dallas, 171) in 1796. The point at issue was whether the tax was direct. If it was, then it could be levied only according to the rule of federal apportionment as prescribed by the Constitution. The court, however, gave a very broad construction of "indirect taxes." It ruled, in effect, that the direct taxes contemplated in the Constitution were but two: a capitation or poll tax; and a tax on land. In the United States these taxes are reserved to the states. The right to levy a land or real property tax is generally delegated by the states to local governments. Neither tax is part of the internal revenue system, therefore.

Between 1794 and 1800, additional excises were levied. They included a liquor retail license fee, and taxes on snuff, sugar, and auction sales. In addition, duties were placed upon legal transactions in the form of stamps to be affixed to the legal documents. Direct taxes were attempted in 1798, with levies on dwellings, lands, and slaves. The results were so indifferent and collections so slow that the attempt was abandoned in 1801. Internal revenue levies were then reduced until 1804, when they were eliminated entirely. They were all re-established in 1814, under the impact of the War of 1812. The volume of revenues, however, declined quickly and sharply, and remained at quite low levels until the outbreak of the Civil War in 1861.

The burden of war financing called forth a whole variety of internal revenue tax measures in 1862. It was noted above that in Great Britain relatively high levies have been placed upon a small number of items. The philosophy of the United States excise and income levies of 1862, on the other hand, was the imposition of moderate duties upon a wide range of items. The contemporary view of David A. Wells aptly described the measure: "Wherever you find an article, a product, a trade, a profession, or a source of income, tax it."

It was after the enactment of this catchall measure that internal revenue briefly exceeded customs duties as a source of federal revenues. Between 1866 and 1870, however, various levies were repealed so that only the excises on spirits and tobacco, stamps on documents, taxes on banks and bankers, modest duties on manufactures, and the income tax remained in the internal revenue system. The income tax expired in 1872. The system then remained stable until 1883. It should be noted that after 1865 internal revenue taxes were repealed in nearly as haphazard a way as they were originally enacted.

In 1883, the stamp duties and the tax on banks and bankers were repealed, leaving only the sumptuary taxes on tobacco and liquor in the internal revenue system. A tax on oleomargarine was enacted in 1887. Inheritance taxes, and stamp and business taxes were instituted in 1898 to help pay for the Spanish-American War.

Income Tax.—The income tax was dealt a serious blow in 1895 when it was declared unconstitutional by the Supreme Court in *Pollack v. Farmers' Loan and Trust Co.* (157 U.S. 429; 158 U.S. 601). This reversed the 1880 decision of *Springer v. United States* which upheld the Civil War income tax. Nevertheless, a corporate in-

come tax was included in the Payne-Aldrich Tariff Act of 1909. It was upheld by the Supreme Court, and has remained an integral part of the United States internal revenue system ever since.

In 1913, the 16th Amendment to the Constitution was ratified, making the income tax constitutional (see *INCOME TAX*). The personal income tax was included in the Underwood Act of 1913. It, too, has remained in the internal revenue system to become the largest single source of internal revenue in the United States.

The advent of social insurance in the 1930's added the Railroad Retirement and Social Security (Payroll) taxes to the internal revenue system. An undistributed profits tax in 1939-1940, and the World War II excess profits tax have since been added to and removed from the tax rolls. The United States internal revenue system is now codified in the Internal Revenue Code of 1954, a complete revision of the American tax structure. It is based largely on the 1939 code, with extensive streamlining and modernization.

Summary.—The United States internal revenue system consists of a few major groups of taxes, as indicated in the following table, which shows their relative importance in comparison with their role in the United Kingdom's inland revenue system.

PERCENTAGE DISTRIBUTION OF INTERNAL
REVENUE RECEIPTS
(1960)

Tax source	United States	Great Britain
Income and profit taxes	70	45
Corporate income	(24)	(22)
Individual income	(46)	(23)
Employment taxes	13	11
Alcohol taxes	4	10
Tobacco taxes	2	15
Estate and gift taxes	2	4
Manufacturers excise taxes	3 }	
All other	4 }	15

The table points up the major difference between the American and British internal revenue (inland revenue) systems. While heavy reliance is placed upon income taxes in the United States, the British depend much more upon excises, or "outlay taxes."

University of Connecticut.

INTERNATIONAL, ĭn-tĕr-nāsh'ŭn-āl or **INTERNATIONALE**, ăn-tĕr-nā-syô-nāl', the name given to the successive labor organizations which originated as the famous International Association of Workingmen. In 1836, a number of German exiles at Paris banded themselves together as a secret society, The League of the Just, with communistic principles. The group of exiles communicated with Karl Marx, and in 1847 held a congress in London where they reorganized and adopted the name of the Communist League. Its leaders commissioned Marx and Friedrich Engels to expound the principles of the

league in the *Communist Manifesto* (q.v.) which appeared shortly before the "February Revolution" of 1848.

In May 1849, Marx, who had been acquitted of high treason and expelled from Prussia, after a brief sojourn in Paris moved to London and settled there for the rest of his life. The league split in 1850 and ceased to exist.

First International.—It was the second International Exhibition of London in 1862 which furnished the occasion, curiously enough, for the founding of the International Association of Workingmen. Besides businessmen from all parts of Europe, a large number of foreign workers, artisans, and craftsmen, were assembled in London in 1862. A number of socialist and labor leaders saw this occasion as an opportunity for the creation of a labor international. Their hopes were realized, and two years later, on Sept. 28, 1864, a great meeting of workmen of all nations was held at St. Martin's Hall, London, under the presidency of Edward Spenser Beesly, the English historian and positivist. Marx was the chief inspirer of the movement; he was assisted by the secretary of Giuseppe Mazzini, Major Wolff—a circumstance from which arose the statement that Mazzini was the founder of the International. As a matter of fact, Mazzini mistrusted the whole affair and soon withdrew from it. A provisional committee was appointed to draw up the statutes of the association; these were to be submitted to a universal congress proposed to be held the next year at Brussels. There were 50 delegates in the committee, in which England, France, Germany, Switzerland, Italy, Poland, and other countries were represented. There was no secrecy about their procedure; it was by the widest publicity that they hoped to spread their propaganda, the dissemination of which was arranged in London.

Thus was born the International Workingmen's Association. Its program was expressed in the "Inaugural Address." To acquire political power, the workers of each country must first of all unite, "take an interest in international politics, watch the diplomacy of their governments closely, and uphold the simple rules of morality in the relations of private persons and of nations." The first congress was not held until 1866, at Geneva; after the second congress at Lausanne in 1867, it spread rapidly and acquired an influence which alarmed the French government. The third congress was convened at Brussels in 1868 and the fourth at Basel, Switzerland, in 1869. On the last of these occasions a number of anarchists attended, headed by the Russian Mikhail A. Bakunin (q.v.).

The International was at the zenith of its power in 1870. In 1872, its congress at The Hague became a battlefield of clashing factions and conflicting ideas. The followers of Marx, with their belief in the necessity of organizing a struggle for political power, clashed with the supporters of Bakunin, who feared centralized power and favored the decentralized and autonomous producers' cooperatives as the economic unit. The Marxists succeeded in transferring the seat of the General Council from London to New York, but the vitality of the International was spent. The final congress of the First International was held at Philadelphia in 1874.

Second International.—The international movement among workers fell into abeyance from the early 1870's until 1889, in which year

the Second International was born at Paris, and its headquarters established in Brussels in 1890. The principal force in the new movement was the German-Social Democratic Party. Almost entirely political in character—as distinct from the economic aspect—it demanded the abolition of standing armies and the creation of international arbitration tribunals. These demands were reaffirmed in Brussels in 1891, at London in 1896, and at Paris in 1900. At the last-named congress Jean Jaurès declared that the organization of international peace and brotherhood was the most important question before the gathering.

The Second International met again in 1904 at Amsterdam during the Russo-Japanese War, when fraternal greetings were sent to the proletariat of both countries and the Socialists and workers of all lands were called upon to oppose with all their might the continuance of war.

Stuttgart was the scene of the next International congress in 1907, when the question of wars and their prevention was again discussed. A resolution was finally passed in which war in general was attributed to competition from markets, militarism, national prejudices, and the desire to weaken the growing power of the working class. Gustav Hervé vigorously advocated a general strike as the most effective weapon to prevent the outbreak of war. A similar measure had been adopted in a resolution by the French Socialist congress earlier in the same year; the Stuttgart assembly, however, being strongly German in element, reflected the German fear of the disrupting influence of the general strike plank, and it was finally resolved that the general strike might be used as a *possible* method of averting war, though not an indispensable one. Militarism again loomed large at the next congress in Copenhagen in 1910. The Stuttgart program was revived and the congress again demanded the Socialist representatives should refuse the means for armament and advocated disarmament, arbitration of international disputes, the abolition of secret diplomacy, and a guarantee of all nations against military attack or suppression by force. A special congress of the Second International was convened at Basel on Nov. 24-25, 1912 to discuss the Balkan situation which threatened to set Europe in flames. This was the last meeting before World War I; in it the working classes of all lands were again urged to use the means which promised to be most efficacious in preventing war, and, in the event of war, to exert themselves to the uttermost to bring it to a speedy conclusion. With prophetic vision the congress declared that if the Balkan imbroglio were allowed to spread, it "would become the most frightful danger to civilization and the workers."

In the light of what was destined to happen only 20 months later—in July 1914—it is interesting to record the solemn admonition of the Basel congress to the Socialists of Austria-Hungary and environs: they were urged "to prevent any attack of the Austrian Monarchy upon Serbia." As all the world now knows, it was exactly an attack upon Serbia which precipitated World War I. The Second International was revived after that conflict ended, supporting socialism throughout the world but excluding Communists from its ranks. With headquarters in London, it adopted the statutes of the Labor and Socialist International (L.S.I.) which sought to attain its objectives by reason rather than by force.

Third International.—Meanwhile, the Third, or Communist International (known generally by the abbreviated "Comintern") was born in Moscow, March 2-6, 1919. From the beginning it was dominated by the Soviet Communist Party and eventually became in fact an arm of Soviet foreign revolutionary policy.

At the congress held in 1922, the Comintern was declared by its spokesmen to be "the revolutionary international of the working classes," and it boldly proclaimed that it stood "squarely for the overthrow of capitalism and the establishment of the workers' and farmers' government throughout the world." It advocated the Soviet form of organization and the dictatorship of the proletariat. The Comintern differed from its predecessors. Instead of an international of autonomous national parties, the Comintern was based upon the view that policies had to be accepted by the national parties and upon the principle of iron discipline and the subordination of national communist parties and their members to the decisions of the governing group in the International. Individuals and groups who refused to accept the dicta from above were ruthlessly purged from the ranks. The seventh and last congress was held in 1935. On May 15, 1943, in the midst of World War II, the executive committee of the Comintern announced its dissolution, and Communist parties in all countries were asked to ratify this step. In 1947 a new International Communist organization was created under the designation of Communist Information Bureau, popularly known as Cominform (q.v.).

The Cominform sought to unify the policies of the Communist parties of different countries, and was the method by which the subordinate parties were controlled. After the death of Joseph Stalin, the Cominform was dissolved (in April 1956) as a gesture of appeasement to Marshal Tito who had been an object of attack as a result of his break with Stalin.

An International Communist Conference was held in Moscow in the fall of 1960, and 81 parties were represented at this secret gathering of top Communist leaders. Twelve were parties in charge of the government of their countries, and the remainder were operating outside of the Iron Curtain. Representatives of all parties present signed the "Peace Manifesto," which bitterly assailed the Western countries, especially the United States. While the doctrine of "co-existence" was proclaimed, the class struggle was not renounced. In fact, the statement emphasized that under conditions of peaceful coexistence favorable opportunities for subversion of friendly countries will inevitably arise. This type of activity is referred to as "the development of the class struggle in the capitalist countries and... intensification of the struggle of the working class." The declaration attacked the West German government and called for opposition to it and support for the communist German Democratic Republic of East Germany.

Labor and Socialist Internationals.—The revived Labor and Socialist International was mainly composed of European Socialist parties which eschewed the use of violence and force for the achievement of political purposes, instead depending upon persuasion and parliamentary means to attain their objectives. The spread of fascism after 1931 gradually undermined these European parties, so that after 1931, only the socialist and labor parties of England, Switzerland, and the

Scandinavian countries survived. As a result no congresses were held after 1931. Exiled socialists from the Continent living in London during World War II continued to meet, and in this fashion a semblance of international unity among socialists was retained.

The first steps toward reestablishing socialist unity were taken in a conference held in May 1946, at Clacton, England. A Socialist Information and Liaison Office (SILO) was set up with an office in Transport House, London. Subsequently a Consultative Committee was organized for an exchange of information, and by the end of 1946 the International Socialist Conference had become a unit within the SILO. A break with the Socialist parties of eastern Europe took place over the endorsement of the Marshall Plan and the cold war. In the meantime, the Consultative Committee had been replaced by the Committee of the International Socialist Conference (COMISCO). The break over cooperation with the Communists and the support of democracy and freedom against the totalitarian powers in the cold war led in 1951 to the transformation of the International Socialist Conference into the Socialist International. The change took place at a meeting in Frankfurt am Main. All parties believing in democratic socialism are eligible to membership. The Socialist International aims to place the means of production in the hands of the people, and it opposes totalitarian communism as a distortion of the Socialist ideal. See also SOCIALISM.

INTERNATIONAL CONFERENCES. Probably as early as 5,000 B.C. conferences were held by the first known city-states in the Tigris-Euphrates cradle of civilization. But international conferences in the sense of meetings of the representatives of nation-states are no older than the state system itself, that is to say a little more than 300 years, calculated from the Peace of Westphalia in 1648.

WESTPHALIA (1648) TO VIENNA (1815)

In marking the end of the Thirty Years' War, the Peace of Westphalia gave a mortal blow to the myth of one universal state, embodied in the Holy Roman Empire, and acknowledged the independence of Switzerland and the Netherlands and the existence of new, independent states in Germany. The conference, which took eight years

to draft the treaty, established the right of states to exist separately and independently. European states were to find it one thing, however, to assert their independence and quite another to maintain it in the face of challenges from successive aspirants to mastery of the Continent: Louis XIV of France (r. 1643-1715), Frederick the Great of Prussia (r. 1740-1786), and Napoleon, emperor of the French (r. 1804-1814). See also WESTPHALIA, PEACE OF.

International conferences marked the end of each of these attempts at European dominance, and they denote successive systems of organizing international life. The next settlements ranking with Westphalia were embodied in a group of separate treaties known collectively as the Peace of Utrecht (1713), which brought the War of the Spanish Succession (1701-1714) virtually to a close. The Conference at Utrecht, which began in 1712, recognized Philip of Bourbon, grandson of Louis XIV, as the Spanish king, but confirmed the permanent separation of the French and Spanish crowns. The ramifications of the settlement affected all of Europe.

Just about a generation later, the status quo was challenged by Frederick the Great of Prussia, who was eager to assert his hegemony over Austria. The War of the Austrian Succession (1740-1748) found France, Bavaria, Saxony, and Spain joining Prussia to attack the realm of Maria Theresa, while England and the Netherlands joined the young queen in an attempt to preserve her throne and the balance of power. This war was not merely a European conflict—it spread to India and to the New World—but despite its global nature, it was indecisive. By the Peace of Aix-la-Chapelle (1748), Frederick did retain Silesia, but Austria was not partitioned, as Frederick had hoped it would be. Nor was the peace enduring, for in 1756, after a major diplomatic revolution, England joined Prussia to combat Austria, France, Russia, and Sweden, in a struggle to determine whether Austria or Prussia would dominate north Germany and whether Britain or France would govern North America and India. The Treaty of Hubertusburg (1763), which concluded the Seven Years' War, gave the laurels to Prussia, and the Treaty of Paris in the same year found Louis XV surrendering to Britain nearly all the French holdings in America.

Napoleon was next to overthrow the existing order, but the Continental state system emerged supreme at the Congress of Vienna (September 1814 to July 1815), which assembled to remake Europe after Napoleon's abdication. The negotiators adopted the principle of legitimacy as their guideline in their attempt to restore the territorial and dynastic arrangements that prevailed before the French Revolution. At the congress, Austria, Britain, Prussia, and Russia decided the major questions, while the other members of the Grand Alliance (Portugal, Spain, and Sweden) played only peripheral roles. The full congress never met officially, most of the work being done in committees.

The congress made extensive territorial settlements in favor of the restored Austrian and Prussian monarchies, formed the Kingdom of the Netherlands, created the Germanic Confederation, divided Poland, assured England of certain colonial possessions, allowed Sweden to keep Norway, reestablished Switzerland as an independent confederation, and restored legitimate dynasties throughout Europe. The congress also laid down

the seven basic rules for classifying diplomatic representatives (protocol of the session of March 9, 1815), which, together with the supplementary (or eighth) rule of the Congress of Aix-la-Chapelle (Nov. 21, 1818), continue with slight changes to be the basic guidelines for international diplomacy.

One decision of the congress that had far-reaching consequences was that riparian states would administer rivers crossing or forming the boundary of more than one of their number, and would regulate river traffic for the benefit of world commerce. The Treaty of Vienna (June 9, 1815) authorized the riparian states along the Rhine to name commissioners to supervise navigation on the river. They were to meet each year to "establish a perfect control" over navigation on the Rhine. The system of creating international organizations to consider problems of common concern was clearly adumbrated at the Vienna meetings. See also VIENNA, CONGRESS OF.

VIENNA (1815) TO VERSAILLES (1919)

The haphazard alignments of the balance of power had since 1648 maintained the community of nations against those with ambitions to dominate all of Europe; but the desire for a more secure arrangement after 1815 led the European powers to fashion the Holy Alliance and the Quadruple Alliance. Both were designed to carry out decisions made at Vienna and to replace war with the conference method as a means of settling future disputes.

The Holy Alliance (q.v.) was the idea of Czar Alexander I of Russia. It bound the signatories who ultimately included all the sovereigns of Europe except the king of England and the pope) "on all occasions and in all places, [to] lend each other aid and assistance; and regarding themselves towards their subjects and armies as fathers of families, . . . [to] lead them, in the same spirit of fraternity with which they are animated, to protect Religion, Peace and Justice." The czar may have hoped that the alliance would presage some form of international security organization. But the only substance this fraternal spirit among Europe's sovereigns acquired came through the Quadruple Alliance (Great Britain, Austria, Prussia, and Russia). The contracting powers stated in the preamble to this treaty of 1815 that they intended "to fix in advance . . . the line of conduct which they propose to follow in order to guarantee Europe against the dangers that might yet threaten her." Each signatory promised to supply 60,000 men should France violate the Treaty of Paris (imposed on her in 1815 after Napoleon's second abdication). The members of the alliance also agreed to "renew at fixed intervals" their previous conferences—"meetings consecrated to great common objects and the examinations of such measures as at each one of these epochs shall be judged most salutary for the peace and prosperity of nations and for the maintenance of the peace of Europe." The four powers planned specifically to meet from time to time to help carry out the terms of the treaties (which involved maintaining garrisons in 17 fortresses on the northern and eastern frontiers of France). These provisions for later meetings were the basis for successive international congresses, a system of international "government by conference" known as the Concert of Europe (q.v.).

The Congress System clearly assumed that the

great powers were the prime movers of world affairs, and that because they alone were strong enough to keep order, they should take the initiative in prescribing the order they proposed to maintain. Resting solidly on the principle that it was desirable to preserve the balance of power and the status quo, the concert promoted the idea of legitimacy (meaning now the right of the dynasties in power to continue to rule rather than give way to revolutionary and subversive ideas about the sovereignty of peoples). The congresses met every few years between 1815 and 1822. At Aix-la-Chapelle (September 1818), the powers disposed of the question of French indemnities and arranged for the allied troops to withdraw from France. They also admitted France to a new Quintuple Alliance and discussed economic and social issues like the slave trade and the status of Jews. In 1820 and 1821, the congresses of Troppau and Laibach considered the revolutions in Spain and Italy. The Austrian diplomat Prince Klemens von Metternich was eager to use force to crush revolutions that threatened to disturb the peace, but his reactionary ideas offended many liberals in Britain and opened up the first major breach in the Congress System. The final break came at the Congress of Verona (October 1822), which considered the situations in Spain and Greece. Britain's refusal to endorse intervention in Spain lest the conflict spread to the Spanish colonies in the new world did not prevent the intervention, but it did bring the Congress System to an end.

The spirit of the Concert of Europe lingered on in the 19th century, however, even after the concert itself had formally ended. Conferences met as crises arose, usually called by the most interested state. The major powers thus found it necessary to consult together about the Eastern Question (q.v.), and they guaranteed the independence of Greece in the London Protocols of 1829 and 1830. They also provided for the neutrality of Belgium (1839) and Luxembourg (1867); they admitted Turkey "to participate in the public law and concert of Europe" at the Congress of Paris (1856); and at the Congress of Berlin (1878) they compelled Turkey and Russia to accept the revision of the Treaty of San Stefano. At the Berlin Conference on African Affairs (Nov. 15, 1884 to Feb. 26, 1885), 14 nations, including the United States, agreed to suppress slavery and the slave trade, declared that the Congo Basin was a neutral area completely open to commerce and that states were free to navigate on the Congo and Niger rivers. The enlarged group of powers also recognized the Congo Free State, with Belgian King Leopold II as its sovereign. No permanent organs emerged from any of these meetings, and every state remained free to decide in each situation whether it would cooperate or not.

The 19th century also saw a growing number of meetings on economic and social questions. Paris was the center of much of this activity. In 1851, 12 powers attended the first International Health Conference there; Paris was also the site of an international conference of 20 states, which in 1856 established the International Telegraphic Union; and in 1863, several states met to discuss international postal problems. Postal matters were also on the agenda of the Congress of Bern in 1874, where representatives of 22 states met to form the General (later "Universal") Postal Union. Similar unions, each of them founded by

a conference, came into being in the fields of health, sanitation, commerce, finance, and humanitarian reform. As of 1911, 45 such organizations existed, all of them created after 1850. Traditional methods of bilateral negotiations and periodic conferences were giving way to more permanent arrangements—to continuing conferences, in effect, in the form of international organizations.

This evidence of increasing international activity gave rise to the hope that states might at last achieve perpetual peace by adopting a "functional approach," that is to say, by developing the widest possible network of nonpolitical ties among themselves and their nationals. These high hopes were to prove illusory, but no more so than the search for world peace through more direct attempts to improve procedures for settling international political differences and stopping the arms race.

The most noteworthy conferences of the latter type were the two Hague peace conferences. (See *HAGUE COURT—Hague Conferences*.) The first (May 18–July 29, 1899) met at the invitation of the Russian czar, who was finding himself hard pressed to keep up with the arms race. At this conference, 26 states agreed to settle international disputes peacefully, but they also took the occasion to define the laws of war. Specifically, they agreed for the succeeding five years not to use projectiles thrown from balloons and not to engage in gas warfare or to employ dum-dum bullets. They also consented to treat their war prisoners and wounded better than they had in the past. They did not, however, actually arrange to disarm or to limit armaments, and though they rejected the idea of compulsory arbitration, they did establish the Permanent Court of Arbitration (popularly known as the Hague Court), which is in effect a congeries of panels of distinguished citizens upon whom states may call as arbitrators.

The Second Hague Peace Conference (June 15–Oct. 18, 1907) was originally to meet in 1904, but ironically it was delayed because of the Russo-Japanese War. When it did meet, it was as unsuccessful as its predecessor in limiting armaments. The British took the lead in proposing disarmament, but the Germans, who did not wish to limit their growing fleet, were the spokesmen for those states who preferred no limits at all. Again the idea of compulsory arbitration was mooted and abandoned, although the conferees did enlarge the machinery for voluntary arbitration, and concluded other conventions on war, neutrality, and the use of force among states to collect debts. The London Naval Conference (December 1907) was the next attempt at limiting war. There 10 naval powers agreed on rules to regulate naval warfare (blockade, contraband, prizes, convoys), but the pact was never ratified.

BETWEEN TWO WORLD WARS

The war that so many had feared while the nations were meeting in vain efforts to save the peace came in 1914. When it was over, the peace conference, held at Paris in the winter of 1919, addressed itself to the task of remaking Europe. The 27 victorious powers designed the peace to be imposed on Germany, but the decisions rested primarily with the Supreme Council (Council of Ten), consisting of President Woodrow Wilson, Secretary of State Robert Lansing, and the prime ministers and foreign ministers of Britain,

France, Italy, and Japan. See also *WORLD WAR I—15. Diplomatic History of the War: The Peace Conferences and Peace Treaties*.

One outcome of the peace conferences was the formation of the League of Nations. It in effect established a continuing diplomatic conference of states committed to protect one another against aggression, to submit disputes to arbitration or inquiry, and to abstain from war until three months after an arbitral award. The League was distinguished from 19th century conferences in having a permanent secretariat and other permanent organs charged with supervising and adjusting the peace.

The League's activities did not obviate the need for other international conferences. For example, the Washington Conference (Nov. 12, 1921–Feb. 6, 1922) met to consider naval armaments and Far Eastern questions. Nine states (Britain, France, Italy, Belgium, Netherlands, China, Japan, Portugal, and the United States) participated and prepared five treaties: the Four-Power (France, Japan, the United Kingdom, the United States) Pacific Treaty, guaranteeing one another's rights in insular possessions in the Pacific and promising to consult if others should threaten these rights; the Shantung Treaty, by which Japan returned Kiaochow to China; two nine-power treaties, guaranteeing the territorial integrity and administrative independence of China and reiterating the principle of the Open Door; and a Naval Armaments Treaty, providing for a 10-year naval holiday limiting the size and number of ships to be built by the United States, United Kingdom, Japan, France, and Italy. In 1930, the London Naval Conference continued international work along these lines, in a document signed by the same five powers, in which they agreed to regulate submarine warfare and to limit the gun caliber of submarines. Limits imposed on building aircraft carriers, provided for in the Treaty of Washington, were extended, and Japan, the United Kingdom, and the United States also agreed to scrap certain warships and to allocate tonnage in other categories. See also *NAVAL CONFERENCES*.

Postwar economic problems also commanded the international stage. Chief among these were the Conference at Genoa (April 10–May 19, 1922) to consider the Russian problem and general world economic questions; two conferences in London (Aug. 7–14, 1922, and Dec. 9–11, 1922) and one in Paris (Jan. 2–4, 1923) to deal with German reparations payments and allied war debts; and still another meeting in London (July 16–Aug. 16, 1924), which adopted the Dawes Plan for reorganizing the German *Reichsbank* under Allied supervision, adjusted reparation payments, and lent 800 million gold marks to Germany. Reparations and debt problems were also the subject of the Lausanne Conference (June 16–July 9, 1932). The principal effort to cope with the world's economic problems was made at a London International Economic Conference (June 12–July 27, 1933), which disregarded war debts and reparations and tried instead to stabilize currencies. That assembly failed, however, largely because President Franklin D. Roosevelt repudiated its efforts in a message to the conference on July 3. See also *REPARATIONS*.

Earlier manifestations of United States isolation, particularly the country's failure to join the League of Nations, had seriously jeopardized the theory and practice of collective security and

led the European powers to make additional attempts to achieve international peace. One of the most important was the Locarno Conference (Oct. 5-16, 1925) where Germany, France, and Belgium signed a treaty endorsing and protecting the Franco-German and Belgo-German frontiers (with Great Britain and Italy acting as guarantors of the pact); the conference also adopted four arbitration treaties between Germany, on the one hand, and Poland, Czechoslovakia, Belgium, and France on the other. In addition, France agreed to assist both Poland and Czechoslovakia in case Germany attacked them. See also LOCARNO, PACT OF.

At a later conference in Paris (August 1928), the Kellogg-Briand Pact (Pact of Paris) was signed, by which the signatories agreed to renounce war as an instrument of national policy. Ultimately over 60 states subscribed, perhaps because the pact involved no sanctions; at least it proved useless in the face of aggression by Japan in China (1931), Italy in Ethiopia (1935), and Germany in Austria and Czechoslovakia (1938) and Poland (1939).

Despite the outbreak of war in the Far East in 1931, efforts at limiting armaments continued at a disarmament conference of 60 nations in Geneva (February-July 1932). France at this time insisted that states create an international police force, but few others were ready to accept so radical an idea. The Disarmament Conference met again in 1933 (Feb. 2-Oct. 14) and discussed some new versions of the old ideas. By this time, however, Adolf Hitler had come to power in Germany (Jan. 30, 1933) and was in no mood to agree to anything short of German equality with the other powers of Europe. Germany withdrew from the Disarmament Conference on October 14 and from the League on October 23; all pre-World War II efforts at disarming came to an end when the conference disbanded on June 11, 1934.

The initiative in international diplomacy now passed to the fascist powers, who proved themselves masters at staging international conferences in ways that guaranteed to them the maximum diplomatic effect. The most notorious of these conferences—and one which for years to come gave a bad name to conferences in general—was the Munich Conference (q.v.) of Sept. 29, 1938, which followed a Nazi campaign of terror and threats. British Prime Minister Neville Chamberlain and French Premier Édouard Daladier met with the German and Italian leaders and agreed that Hitler should take 10,000 square miles of Czechoslovakian territory, with about 3,500,000 inhabitants. This sacrifice, widely hailed as the price of peace, ultimately proved to be an act of appeasement that enlarged Hitler's appetite and led him less than a year later to attack Poland and thus to open the second world war.

ORGANIZING THE UNITED NATIONS SYSTEM

Even while World War II was in progress, international meetings were being held to organize the peace. An Inter-Allied Declaration, signed June 12, 1941, at St. James's Palace, London, by representatives of five states (Great Britain, Canada, Australia, New Zealand, and the Union of South Africa) and nine governments in exile (Belgium, Czechoslovakia, Greece, Luxembourg, the Netherlands, Norway, Poland, Yugoslavia; and Gen. Charles de Gaulle of France), declared that "the only true basis of enduring peace

is the willing cooperation of free peoples in a world in which, relieved of the menace of aggression, all may enjoy economic and social security." The statesmen pledged that they would "work together, and with other free peoples, both in war and peace, to this end." On Aug. 14, 1941, President Roosevelt and Prime Minister Winston Churchill signed the Atlantic Charter "somewhere in the Atlantic" (actually Placentia Bay, Newfoundland), and expressed their hopes for a world free from fear and want. They endorsed disarmament and the fullest collaboration among states to improve labor standards and to help the world advance in economic and social matters. These objectives were endorsed by the representatives of 26 nations on Jan. 1, 1942, at Washington, D.C., in the so-called "Declaration by United Nations."

More details about the shape of the postwar world emerged as the war progressed. At Moscow, on Oct. 30, 1943, representatives of China, the USSR, the United Kingdom, and the United States declared that the four governments "recognized the necessity of establishing at the earliest practicable date a general international organization, based on the principle of the sovereign equality of all peace-loving states, and open to membership by all such states, large and small, for the maintenance of international peace and security." And on December 1 of that year, President Roosevelt, Premier Joseph Stalin, and Prime Minister Churchill acknowledged at their meeting at Teheran, Iran, that they had the "supreme responsibility . . . to make a peace which will command the goodwill of the overwhelming masses of the peoples of the world and which would banish the scourge and terror of war for many generations." See also WORLD WAR II—14, *Diplomatic History*.

These generalizations found their way into more specific proposals for a postwar United Nations organization at a conference at Dumbarton Oaks in Washington, D.C. The meetings were held in two parts (Aug. 21-Sept. 28, 1944, for representatives of the USSR, the United Kingdom, and the United States; and Sept. 29-Oct. 7, 1944, for representatives of China, the United Kingdom, and the United States). Afterward, the powers made public the design of a world organization with a Security Council on which the Big Five (China, France, the USSR, the United Kingdom, and the United States) would be permanently represented. At Yalta, USSR, at a meeting of the United States, British, and Soviet leaders, on Feb. 11, 1945, the Big Three agreed that "a conference of United Nations" should be called to meet at San Francisco on April 25, 1945, to prepare the charter of an organization, along the lines proposed in the informal conversations of Dumbarton Oaks.

Despite Roosevelt's death on April 12, the San Francisco Conference, with 50 nations present, met as scheduled between April 25 and June 26, 1945, where the plans laid at Dumbarton Oaks and Yalta were modified by the conference itself and resulted in the Charter of the United Nations and the Statute of the International Court of Justice. See also UNITED NATIONS.

Other international conferences marked the origins of many new intergovernmental organizations associated with the United Nations: Food and Agriculture Organization (FAO)—Hot Springs, Va., May 1943; International Bank for Reconstruction and Development and Interna-

tional Monetary Fund—Bretton Woods, N.H., July 1–22, 1944; International Civil Aviation Organization—Chicago, Ill., Nov. 1–Dec. 7, 1944; International Atomic Energy Agency—United Nations, New York, Sept. 20–Oct. 26, 1956; Intergovernmental Maritime Consultative Organization—Geneva, March 6, 1958; United Nations Education, Scientific and Cultural Organization (UNESCO)—London, Nov. 1–16, 1945; World Health Organization (WHO)—New York, July 1946.

Aside from being a continuing conference itself, the United Nations has called special conferences on many important topics. Among them have been:

(1) Conference on Freedom of Information (1948), in Geneva, which prepared three draft conventions on gathering and transmitting news, on freedom of information, and on the right of correcting inaccurate reports.

(2) Scientific Conference on the Conservation and Utilization of Resources, attended by experts from over 50 countries, held at Lake Success, New York, Aug. 17–Sept. 6, 1949.

(3) Two United Nations international conferences on the Peaceful Uses of Atomic Energy (Aug. 8–20, 1955 and Sept. 1–13, 1958), which studied the development of atomic power and other activities suitable for effective international cooperation, such as biology, medicine, and radiation protection; both conferences met in Geneva and were attended by scientists from about 70 states each time.

(4) A two-week World Food Congress (June 1963), in Washington, which took up the challenge of eliminating hunger and malnutrition in the world.

(5) Commodity conferences every few years to regulate (or discuss the possibility of regulating) the markets in tin, coffee, sugar, wheat, olive oil, cocoa, copper, lead, and zinc.

PEACEMAKING AFTER WORLD WAR II

When the second world war ended, the great powers attempted to settle the peace in a series of international conferences. Peacemaking in the postwar world was to be no easy task, however, and the process of liquidating the issues raised by World War II was still going on nearly two decades after hostilities ceased.

Procedure.—The Council of Foreign Ministers was the principal group concerned with postwar problems. Established at the Potsdam Conference (July 17–Aug. 2, 1945), the Council comprised the representatives of the five victorious great powers who were also the permanent members of the U.N. Security Council. They were ultimately to meet eight times between 1945 and 1954 in efforts to agree among themselves on the shape of the postwar world. The Paris Peace Conference itself was held from July 29 to Oct. 15, 1946.

MEETINGS OF THE COUNCIL OF FOREIGN MINISTERS

Dates	Place
Sept. 11–Oct. 2, 1945	London
Dec. 16–26, 1945 (interim meeting)	Moscow
April 25–May 16, and June 15–July 12, 1946	Paris
Nov. 4–Dec. 12, 1946	New York
March 10–April 24, 1947	Moscow
Nov. 25–Dec. 16, 1947	London
May 25–June 21, 1949	Paris
Jan. 25–Feb. 18, 1954	Berlin

The council was to prepare the proposals for the final peace settlements with Italy, Rumania, Bulgaria, Hungary, Finland, Austria, and Germany. Early in the council meetings, a procedural problem arose that delayed matters considerably and fundamentally affected the council's work. The Potsdam protocol provided that only the signatories of the surrender terms could "discharge . . . these tasks" of making the treaties. Neither France nor China had been signatories, although the Potsdam agreement specifically stated that France might be a party to the discussions in the case of the Italian treaty. Nonetheless, on Sept. 22, 1945, the USSR objected that the council's original decision of September 11 to allow China and France to discuss all the treaties was illegal.

The United States maintained that everyone had understood at Potsdam that even the non-signatories might discuss the treaties, although only the signatories could vote. United States Secretary of State James Byrnes then tried to compromise with the Soviet Union by agreeing that France and China would not continue discussing the treaty principles if in turn the USSR would allow the final peace treaties with the five countries to go before a peace conference of all European members of the U.N. and all non-European states that had supplied substantial military contingents in the war against the European members of the Axis.

At the interim meeting of the council in Moscow, later in 1945, the ministers in effect adopted the Byrnes compromise. They agreed with the USSR to abide by the letter of the Potsdam Agreement and to allow only those states that signed the armistices to draw up the original drafts. But they also endorsed the American plan to permit the drafts to go before a general peace conference. The conference would then consider the drafts and prepare its own recommendations. The Big Three (or Four, in the case of the Italian treaty) would next consider the conference's recommendations and prepare the final texts, which all states would sign. This plan did not give all the belligerents as much of a hand in making the peace treaties as they might desire, but it did allow them all to criticize the proposals of the larger powers.

Thus it was that at the second part of their first meeting in Paris the ministers agreed to call a peace conference, to open in Paris on July 29, 1946. At that time 21 nations met in Paris to put their seal on the work of the Big Four. With the conference's recommendations in hand, the council then met in New York to complete the texts of the peace treaties with the five states.

The Italian Treaty.—The Italian treaty was on the foreign ministers' agenda in 1945 and 1946. The principal questions on which the USSR and the Western powers differed related to reparations, the former Italian colonies, and the Italian-Yugoslav boundary, particularly as it concerned the city of Trieste. A compromise was reached on the reparations problem. The council never was able to agree about the colonies, and they ultimately allowed the U.N. General Assembly to dispose of them in 1949. The Trieste question lingered on until October 1954, when Italy, the United Kingdom, the United States, and Yugoslavia signed the London Memorandum of Understanding, defining the jurisdiction of both Italy and Yugoslavia in the area.

The Finnish and Balkan Treaties.—The United States maintained that the Bulgarian and

Rumanian governments did not represent their people and did not allow all of them to enjoy basic human rights. The ministers then agreed on certain steps to broaden the base of the two Balkan governments. The Soviet Union argued against including in the treaties any terms that would promise freedom of commerce on the Danube; and the USSR also insisted on limiting the economic contacts between the Central European states and the rest of the world. By the terms of the Belgrade Convention of Aug. 18, 1948, a treaty signed by the USSR and her Balkan satellites, an end was put to the nearly 100-year old internationalized regime on the Danube. The treaties included provisions calling for reparations for the USSR of \$300 million (in 1938 prices) in commodities from Rumania, Hungary, and Finland, and \$70 million from Bulgaria.

German and Austrian Treaties.—By agreement at New York, the German and Austrian questions came before the foreign ministers at their 1947 meeting in Moscow. In these negotiations, all the disagreements so evident during the conferences on the Italian and Balkan treaties came into sharp focus and remained in effect unsolved. The foreign ministers agreed that they should lay the foundations for a central government for Germany; bring about the economic unity of Germany; establish workable boundaries; and set up a guaranteed control through a four-power treaty. Austria was to be promptly relieved of occupation burdens and treated as a liberated and independent country.

When it came to translating these general principles into specific treaties, however, the foreign ministers were far apart. Generalissimo Stalin told United States Secretary of State George C. Marshall that the Moscow meetings were really just the first skirmishes and brushes of reconnaissance forces on the German question, and that compromise would come, but only after people had exhausted themselves in dispute. And by and large, the London meetings, held later in the year, were but a dreary repetition of what had been said and resaid in Moscow. The central question was whether Germany was to continue divided or whether the Allies could agree on how to unify their former enemy. The United States wanted the Soviet Union to eliminate the artificial zonal barriers and permit persons, ideas, and goods to move freely through all of Germany. With certain basic problems solved, the West believed that they could establish a provisional government for Germany. The USSR, however, refused to supply information either about reparations it had already taken out of east Germany or about economic conditions there, and thus made it impossible even to consider the German question in a preliminary way. The USSR refused to consider the boundary question and called instead for the powers to establish a central German government immediately. To the West, Russia's refusal to proceed in a logical order indicated that the Soviet Union was using the meeting as an opportunity to make propaganda declarations that sounded pleasant to German ears. Although a peace treaty with Austria was finally signed in 1955, no peace treaty had been signed with Germany as late as 1963.

Japan.—In 1947 the United States proposed a preliminary conference of the Big Five, Australia, Canada, India, the Netherlands, New Zealand, and the Philippines to consider plans for a Japanese peace treaty. The USSR insisted, how-

ever, that only the Council of Foreign Ministers (where they had a veto) could consider the treaty. The United States therefore decided to abandon the conference method, which afforded so many possibilities for the USSR to obstruct proceedings, in favor of negotiation through successive bilateral discussions that no single nation could thwart.

In June 1951, after having consulted with the states concerned, the British and Americans prepared a joint draft agreement. The Soviet Union took an active but reluctant part in the proceedings. From September 4 to September 8 the nations gathered in San Francisco to sign the treaty, which restored sovereignty to Japan and was, in general, not vindictive. Peace between Japan and China and the disposition of certain territories were left to the future. And since the USSR refused to sign the treaty, the problem of peace between Japan and the USSR also remained unsettled until they signed separate agreements in the fall of 1956.

For a further discussion of the World War II peace treaties, see *WORLD WAR II—15. Postwar World*.

SECURITY TREATIES

Increasing Soviet hostility in diplomacy, her assistance to the forces of international communism, the coup in Czechoslovakia and the Berlin Blockade in 1948, and the outbreak of hostilities in Korea in 1950—all these developments forced the West to look to its defenses in the postwar period.

One of the most important meetings for the security of the Western Hemisphere took place at Rio de Janeiro, Brazil; the Conference for the Maintenance of Continental Peace and Security (Aug. 15–Sept. 2, 1947), which 21 American states attended, produced the Inter-American Treaty of Reciprocal Assistance (ratified by the United States on Dec. 19, 1947). The treaty stated (Article 3) that “an armed attack by any State against an American State shall be considered as an attack against all the American States and, consequently, each one of the . . . Contracting Parties undertakes to assist in meeting the attack in the exercise of the inherent right of individual or collective self-defense recognized by Article 51 of the Charter of the United Nations.” And at their Ninth International Conference, in Bogotá, Colombia (March 30–May 2, 1948), the American states adopted the Charter of the Organization of American States (OAS), a revised and strengthened regional organization with responsibilities for defense, and economic and social development.

That same year five European nations (Britain, France, Belgium, the Netherlands, and Luxembourg) met at Brussels (March 17, 1948) to sign a 50-year defense pact, by which they agreed to aid one another should an aggressor (they had Germany in mind) attack. And on April 4, 1949, the representatives of 12 Western nations (Belgium, Canada, Denmark, France, Iceland, Italy, Luxembourg, the Netherlands, Norway, Portugal, the United Kingdom, and the United States) met in Washington to sign the North Atlantic Treaty. Building on the formula of the Rio Pact and the example of the Brussels organization, the North Atlantic Treaty Organization (NATO) powers agreed that “an armed attack against one or more of them in Europe or North America shall be considered an attack against them all,” and

pledged themselves to take such action as each deemed necessary, "including the use of armed force," in case of attack.

So that Germany might be included in the defense of the West, the British arranged, through a series of conferences in London and Paris in September and October 1954, to have the five Brussels Pact powers invite Italy and the Federal Republic of Germany to join them in a new defense arrangement known as the Western European Union (WEU). Through WEU they established certain controls over Germany's armed forces and armaments (such as denying Germany access to atomic, bacteriological, and chemical weapons), and thus created an organization that permitted Germany to have her independence and to join NATO. See also NORTH ATLANTIC TREATY and WESTERN EUROPEAN UNION.

In the Pacific area, several interrelated pacts entered into force on April 15, 1952, at the same time as the Japanese Peace Treaty. Each of these was arranged in separate conferences with the parties concerned. One was a security treaty between the United States and Japan (signed Sept. 8, 1951 and revised in 1960); another was a treaty between Australia, New Zealand, and the United States (the ANZUS Pact, signed Sept. 1, 1951). The United States signed two other bilateral security treaties, one with the Republic of Korea (Oct. 1, 1953) and another with the Republic of China (Formosa) on Dec. 2, 1954. Capstone of the Pacific defense arrangements was the Southeast Asia Treaty Organization (SEATO, q.v.) to Cambodia, Laos, and North Vietnam. The multitude of Pacific treaties contrasts sharply with the more unified European security design. The more complex pattern was essential, however, because the three countries that had been victims of Japanese aggression were reluctant to join in a mutual security pact with Japan. Moreover the Pacific powers could not agree on the areas they were all prepared to defend.

The final link in the United States-designed network of security treaties came in 1955 with the development of the defensive alliance system known as the Baghdad Pact. Iran, Iraq, Turkey, Pakistan, and the United Kingdom were the signatories. When Iraq defected after a revolution in July 1958, it was renamed the Central Treaty Organization (CENTO, q.v.), with new headquarters in Ankara, Turkey.

On the Communist side, there was no comparable international complex of security treaties, but the Communist powers held several important conferences. Pursuing its vigorous anti-Western line, the USSR took the lead in September 1947 in Warsaw in establishing a new international Communist center, the Communist Information Bureau (Cominform) to link the Communist parties of the Soviet Union and the East European states together with the important western Communist parties in France and Italy. The Cominform was dissolved, however, on April 17, 1956, as a conciliatory gesture toward Yugoslavia. On Feb. 14, 1950, at a meeting in Moscow, the Chinese and Soviet leaders signed a mutual defense treaty. In May 1955, Albania, Bulgaria, Czechoslovakia, Hungary, East Germany, Poland, Rumania, and the USSR signed a 20-year

treaty of friendship, cooperation, and mutual assistance at Warsaw. The Warsaw Pact signatories argued that the treaty was necessary because "of a new military alignment in the shape of 'Western European Union,' with the participation of a remilitarized Western Germany and the integration of the latter in the North Atlantic bloc."

ARMISTICE AGREEMENTS

Security treaties notwithstanding, hostilities broke out to plague the postwar world and international conferences were essential to establish armistices in all these areas.

Arranging an armistice in Korea after hostilities broke out there on June 25, 1950, proved a prolonged matter. Negotiations began between opposing military commanders on June 10, 1951, at Kaesong in Korea. On October 25 they were reopened in the Korean town of Panmunjom. They continued until Oct. 8, 1952, when they were recessed indefinitely because of disagreement about the repatriation of the prisoners of war. The two sides did agree to exchange sick and wounded prisoners in April 1953; negotiations reopened and an armistice agreement was signed on July 27, 1953.

The problems of Korea and Indochina were the subjects of a conference at Geneva (April 26–July 21, 1954), agreed upon by the Conference of Foreign Ministers the February before. The 16 countries that had taken part in the Korean hostilities on the U.N. side (Australia, Belgium, Canada, Colombia, Ethiopia, France, Greece, Luxembourg, the Netherlands, New Zealand, Philippines, Republic of Korea, Thailand, Turkey, the United Kingdom, and the United States), as well as North Korea, the People's Republic of (Communist) China, and the USSR, participated in the Korean phase of the conference. But the attempt to carry out the U.N. resolutions calling for a unified, independent, and free Korea foundered, according to a declaration issued June 15, 1954, by the members of the U.N. command, because the Communist delegations refused to recognize the authority of the U.N. and would not accept impartial and effective supervision of elections in the country.

Representatives of eight governments—Cambodia, the Democratic Republic of (North) Vietnam, France, Laos, the People's Republic of (Communist) China, the State of (South) Vietnam, the USSR, and the United Kingdom—and the United States took part in the Indochinese phase of the conference. The eight issued a Final Declaration on July 21, 1954, taking note of agreements ending hostilities in Cambodia, Laos, and Vietnam and organizing international control and supervision of the armistice arrangements. In a separate statement, the United States associated itself with all but one paragraph of the Final Declaration, paragraph 13, which bound the conferees to meet again to consult one another on any question referred to them by the International Supervisory Commission (Canada, India, and Poland).

Deteriorating conditions in Laos led to another conference in Geneva, this time of 14 nations, which met intermittently from May 16 to Dec. 4, 1961, and which took two steps toward guaranteeing the independence and neutrality of Laos. The conferees approved international investigatory procedures for the Southeast Asian kingdom and charged the United Kingdom and

the USSR with the responsibility of supervising the treaty.

CONTROL OF ARMAMENTS

Since World War II, the major powers, compelled by the awesome nature of atomic weapons, have negotiated intermittently on disarmament and have been under constant pressure from the United Nations to resume talks each time a recess has threatened to go on too long. From 1947 to 1952, the principal forums for the attempts to regulate armaments were the U.N. Atomic Energy Commission and the Commission for Conventional Armaments. After 1952, the work of these two bodies was combined in a single Disarmament Commission, whose members (1952-1958) were the Security Council members and Canada (when Canada was not a member of the Security Council). In addition, from 1954 to 1957 a Subcommittee of Five (Canada, the United Kingdom, the United States, the USSR, and France) was the principal forum for disarmament talks. When this group reached a stalemate in 1957, the United Nations attempted to keep the talks going by enlarging the Disarmament Commission to give it 25 members, but the USSR refused to participate, arguing that the commission was still not representative enough. But when the membership was made identical with that of the United Nations, the commission became too unwieldy for any talks. In fact, 1957 is the last year, and the Subcommittee of Five the last body, in which meaningful disarmament talks actually took place directly within the United Nations.

Thereafter, the U.N. General Assembly continued to urge the powers concerned to carry on their conversations outside the world organization. This they have done in various ways. In 1958 Soviet and American experts conferred in two gatherings on how to avoid surprise attacks (Nov. 10-Dec. 18, 1958) and how to detect violations of a nuclear test ban (July 1-Aug. 21, 1958). On Oct. 31, 1958, the Geneva conference on discontinuing nuclear tests began among the United States, the United Kingdom, and the USSR. A 10-nation committee (5 from the East and 5 from the West) outside the United Nations started work on disarmament on Sept. 7, 1959. In June 1960 the Soviet Union refused to continue negotiating, however, allegedly because the United States U-2 "spy flights" over the USSR had proved to them that the West was not sincere in their efforts to disarm. From 1960 to 1962, therefore, no disarmament talks took place. But in 1962, the 10-nation committee was enlarged to 18, to include 8 neutralist states. (France, though a member, refused to participate.)

On June 21, 1963, the Disarmament Conference in Geneva recessed to allow for a three-power discussion on a nuclear test ban in Moscow. On August 5, a treaty prohibiting nuclear testing in the atmosphere, in space, and under water was signed in Moscow by United States Secretary of State Dean Rusk, Soviet Foreign Minister Andrei A. Gromyko, and the Earl of Home, British foreign minister. A communique issued at the time of the signing stated that the three governments considered this only a first step toward peace; others were invited to join the treaty. Although underground testing was not prohibited, the treaty pledged the three powers to continue negotiations for the discontinuance of all nuclear testing of all kinds.

See also DISARMAMENT.

ECONOMIC CONFERENCES

International conferences on economic problems in the postwar period produced more agreement than the meetings devoted to military matters. In a speech at Harvard University on June 5, 1947, Secretary of State George C. Marshall invited European countries to agree upon a recovery program that the United States could support. Within two days the British foreign minister, Ernest Bevin, was consulting in Paris with Georges Bidault, his French counterpart, about such a plan. They invited Soviet Foreign Minister V. M. Molotov to join them, and the three discussed European recovery in Paris from June 27 to July 3, without coming to any agreement on a common approach. The Soviet position was that each European state should give the United States its individual request for economic assistance; Molotov flatly refused to agree that a plan of intra-European assistance was desirable or possible. The British and French governments then invited all the European states (except Germany, Spain, and the USSR) to meet in Paris on July 12, 1947, to prepare a joint program embodying Europe's needs, resources, and requirements.

The invitation was accepted by 14 states (Austria, Belgium, Denmark, Greece, Ireland, Iceland, Italy, Luxembourg, Norway, the Netherlands, Portugal, Sweden, Switzerland, and Turkey). These established a Committee for European Economic Cooperation, comprising a representative of each state, and an Executive Committee of five states. The representatives prepared a comprehensive program covering four years, 1948 to 1951, which the conference adopted on Sept. 22, 1947, and forwarded to Washington. Later negotiations conducted by Britain and France led to a second meeting of the committee in Paris in March 1948. This conference in turn produced the Convention on European Economic Cooperation, which was signed in Paris on April 16, 1948, and established the Organization for European Economic Cooperation (OEEC). See also ECONOMIC COOPERATION ADMINISTRATION, THE.

The economic and military efforts to unite Europe had counterparts on the political side, although the initiative for a political union lay with private groups rather than with governmental authorities. A "Congress of Europe" met at The Hague from May 8-10, 1948, comprising 713 delegates from 16 countries and observers from 10 others. The congress attempted to demonstrate how wide the support for European unity was. The president of honor was Sir Winston Churchill, and the participants included other former governmental, parliamentary, and civic leaders. They adopted resolutions calling for an economic and political union in Europe, and in September 1948, the Belgian and French governments submitted these proposals to the Permanent Council of the Brussels Treaty powers. After referring the matter to a five-power "Committee for the Study of European Unity," the Brussels powers agreed in January 1949 to set up a Council of Europe, consisting of a ministerial committee meeting in private, and a parliamentary body meeting in public. The powers also agreed to convene a conference of ambassadors to work out the details and invited five other countries (Ireland, Italy, Denmark, Norway, and Sweden) to join the talks. Negotiations continued in London and resulted in the Statute of the Council of

Europe, signed on May 5, 1949. See also EUROPE, COUNCIL OF.

International conferences have brought into being a variety of European regional arrangements: the European Payments Union (EPU, q.v.) on Sept. 19, 1950; the European Coal and Steel Community (ECSC, q.v.) on April 18, 1951; and the European Community on March 10, 1953. The Statute for the European Community was drafted by a constitutional committee, various subcommittees, and a "working party," formed by the Common Assembly of the ECSC at the invitation of the six ministers for foreign affairs of the ECSC countries. These groups met from Sept. 15, 1952, until Feb. 25, 1953, preparing the draft treaty.

All these preliminary arrangements paved the way for the European Economic Community (EEC, q.v.), known as the Common Market. Plans for this important organization were drafted by the foreign ministers of "Little Europe" (Belgium, France, West Germany, Italy, Luxembourg, and the Netherlands) at Messina, Italy, in June 1955. They then established an Intergovernmental Conference, which met in Brussels through the winter of 1955-1956 with Paul-Henri Spaak, foreign minister of Belgium, in the chair. In April 1956 the conference produced a report suggesting how the "Six" might create a customs union and an agency for exploiting atomic energy. The foreign ministers approved the report in Venice in May 1956 and issued instructions for drafting the treaties, which the Brussels Conference set about doing. Early in 1957 they completed their work, and the treaties establishing the EEC and the European Atomic Energy Community (Euratom, q.v.) were signed in Rome on March 25, 1957. The two communities came into existence on Jan. 1, 1958. Both provided for executive, parliamentary, judicial, and intergovernmental organs, like those of the ECSC, although the powers of the executive bodies were not so great as those of the latter. A European Free Trade Association (EFTA, q.v.) was created by the Treaty of Stockholm and came into being on May 3, 1960, to coordinate trade policies among the "Outer Seven" (Austria, Denmark, Norway, Portugal, Sweden, Switzerland, and the United Kingdom), states not in the Common Market.

A charter for a new Organization for Economic Cooperation and Development (OECD) was drafted in Paris in November 1960, to take effect on Sept. 30, 1961 and to replace the OEEC. The OECD planned to work to speed economic growth, to increase employment, to help its members aid underdeveloped areas, and to expand multilateral, nondiscriminatory world trade. It has 20 members (all of Western Europe plus Canada, Turkey, and the United States).

A series of international conferences have been held under the provisions of the General Agreement on Tariffs and Trade (GATT), drawn up in 1947 at Geneva. In addition to regular sessions to work out detailed procedures, GATT has held several major tariff conferences: in 1949 at Annecy, France; in 1950-1951 at Torquay, England; in 1956, 1960-1961, and 1963 at Geneva. These conferences have helped reduce or stabilize duties on tens of thousands of items in international trade. All countries adhering to GATT have taken part in these tariff negotiations; in fact states adhering to GATT have to undertake to reduce their own tariffs beforehand.

ASIAN AND AFRICAN CONFERENCES

Not all contemporary international conferences have been held by nations traditionally prominent in diplomacy. The first large-scale Afro-Asian conference was held at Bandung, Indonesia, in April 1955. The participants included the "uncommitted" Afro-Asian states, the Asian members of SEATO, and the Communist states of China and North Vietnam. Racist undercurrents were apparent at Bandung, but the conference's principal formal action was to endorse the "five principles of coexistence," the *Panch Chila*, which Prime Minister Jawaharlal Nehru of India and Communist Chinese Foreign Minister Chou En-lai had subscribed to in a Sino-Indian agreement on Tibet on April 29, 1954. These principles were: (1) mutual respect for each other's territorial integrity and sovereignty; (2) mutual nonaggression; (3) mutual noninterference in internal affairs; (4) equality and mutual benefit; and (5) peaceful coexistence. The Bandung Conference symbolized the advent of the Asian-African states on the world stage as a force the rest of the world could no longer ignore.

In the fall of 1961, the Afro-Asian states met in Belgrade on the invitation of Marshal Tito, who had earlier in the year toured Africa extensively. A preparatory conference in Cairo (June 1961) worked out the qualifications for attending the Belgrade Conference; it was decided that states would not be invited just because they were members of a geographical region, but only if they were "noncommitted." As defined in Cairo, the term was applied to states that were independent of the two major power blocs, that displayed "clear tendencies and efforts" to sustain such a policy of independence, that tried to coexist with states of different social systems, or that, even if they were members of military alliances, gave evidence of being free from involvement in conflicts. The Belgrade Conference of the "nonaligned" excluded African states closely associated with France, but invitations went to Austria, Sweden, and Ireland (all of whom declined) and several Latin American states. Of these, Cuba sent a fully accredited delegate, and three (Brazil, Bolivia, and Ecuador) sent observers.

The movement for cooperation among the African states alone gained momentum after Ghana became independent in 1957. The first conference of Independent African States was held in Accra, Ghana, in 1958 with eight states participating (Ethiopia, Ghana, Liberia, Libya, Morocco, Sudan, Tunisia, and the United Arab Republic). Since then, the African states have split into two groups, the so-called Brazzaville Group (named for a meeting in that city in December 1960, attended by 12 states formerly under French rule) and the Casablanca Group (which takes its name from a meeting in that city in January 1961, attended by Ghana, Guinea, Mali, Morocco, the United Arab Republic, Libya, Ceylon, and the Algerian nationalists; the last three were not invited to sign the charter, but they took part in the deliberations). The Brazzaville Group, receiving considerable aid from France, adopted a "moderate" view of the Congo and Algerian questions. The Casablanca Group supported the factions backing Patrice Lumumba in the Congo and generally took a militant anticolonial line. They attacked the Brazzaville states as dupes of the former colonial powers, whom they ac-

cused of attempting to divide and thus control Africa.

A still wider grouping developed in May 1961, when the Brazzaville states met with seven other African countries at Monrovia, Liberia, where Nigeria played a leading role. The Casablanca Group refused to attend both this conference and another held at Lagos, Nigeria, in January, 1962. In meetings held in Addis Ababa, Ethiopia, in May 1963, African states formed the Organization for African Unity, an all-African association with a secretariat, a council of ministers, and a commission to mediate disputes between African states. Kwame Nkrumah, president of Ghana, failed to persuade the conference that Africa unite immediately under a federal government. A more moderate position, which ultimately found expression in the charter adopted by the conference, was espoused by Ethiopia, Nigeria, and Tanganyika. See also AFRICA—12. *Emergence of Modern Africa*.

RICHARD N. SWIFT,
Professor of International Relations, New York University.

INTERNATIONAL COURT OF JUSTICE, judicial organ of the United Nations, frequently referred to as the **WORLD COURT**. This agency for settling international legal disputes and strengthening international law was successor to the Permanent Court of International Justice (q.v.), which had been created by the League of Nations in 1920 but, with the latter, was discontinued after World War II. The statute of the new World Court, which formed part of the Charter of the United Nations adopted in 1945 (see UNITED NATIONS), was almost identical with that of the old court. It was opened automatically only to members of the United Nations, thus excluding some parties to the old court statute not originally admitted to the latter organization. Nonmembers may, however, become parties to the statute of the court on conditions determined by the General Assembly on recommendation by the Security Council. Switzerland, Liechtenstein, and San Marino have taken advantage of this opportunity. Furthermore, the court is open to states not parties to the statute on conditions laid down by the Security Council.

The 15 judges, nominated so as to assure the competence of all in international law and the representation of each of the principal legal systems of the world, are elected by concurrent votes of the United Nations General Assembly and Security Council without great-power veto in the latter body. The earlier court met once a year only for a stipulated term, but the new court is in permanent session.

The United States never became a member of the League of Nations nor a party to the statute of the Permanent Court of International Justice, but it was an original member of the United Nations and, therefore, party to the court statute from the beginning. Furthermore, the United States accepted the compulsory jurisdiction of the court in 1946, but with the Senate's Connally Reservation, giving it discretion to exclude the exercise of that jurisdiction in any case which it regarded as within its domestic jurisdiction.

At the first session of the General Assembly and Security Council in 1946, the judges were elected, 5 for a full nine-year term, and 5 each for six and three years respectively. The American judge elected was Green H. Hack-

worth, former legal adviser to the State Department, succeeded in 1961 by Philip C. Jessup of Columbia University, formerly United States ambassador-at-large. The other 14 judges came from Belgium, Brazil, Canada, Chile, China, Egypt, El Salvador, France, Great Britain, Mexico, Norway, Poland, the Soviet Union, and Yugoslavia. After the election of 1961, judges from Argentina, Australia, Greece, Italy, Japan, Panama, and Peru had replaced those from Brazil, Canada, Yugoslavia, Belgium, Norway, El Salvador, and Chile.

The salaries of the judges were fixed at 44,000 Dutch guilders a year, with a special allowance of 15,000 guilders for the president of the court and a maximum of 10,000 for the vice president. The first meeting of the International Court of Justice was held in April 1946, at The Hague, seat of its predecessor.

The court, like its predecessor, has contributed much to the development of international law, but it has been used less frequently than was the earlier court in spite of a resolution of the General Assembly in 1947 urging more frequent use. A committee of the American Bar Association on World Peace Through Law has urged repeal of the Connally Reservation and American initiative toward greater use of the court.

QUINCY WRIGHT,
Professor Emeritus of Foreign Affairs, University of Virginia.

INTERNATIONAL DATE LINE, an irregular line roughly coincident with the 180th meridian of longitude on maps of the world, and used to adjust for the necessary difference of one day in time in traveling either eastward or westward around the full circumference of the earth. This adjustment is made necessary by the fact that in proceeding eastward or westward, the time becomes respectively one hour later or earlier for each 15° of longitude covered. If the entire circumference (360°) of the earth is traversed, a full day (24h) is thus gained or lost. The location of the date line in the middle of the Pacific Ocean, exactly opposite (in the antipodes) from the *prime meridian* of Greenwich, provides a convenient location in which to make the change of date without confusion in the affairs of everyday life. Actually, the line deviates around certain small land masses to avoid separating component islands of a group or an archipelago from each other or from the time zone of their protectorate country. In crossing the date line from east to west, the date becomes one day later (for example, the date Monday, March 21 becomes Tuesday, March 22); in crossing the date line eastward, the date becomes a day earlier (thus Thursday, September 21 becomes Wednesday, September 20). Although now generally recognized by all countries, the International Date Line has not been officially adopted as was the prime meridian of Greenwich at the International Meridian Conference held in 1884 in Washington, D.C. See also TIME, INTERNATIONAL ZONES OF.

FERGUS J. WOOD,
Physical Scientist, Office of the Director, United States Coast and Geodetic Survey.

INTERNATIONAL EDUCATION. If given its broadest meaning in current usage, the term "international education" denotes all kinds of educational relations among nations. Thus in-

ternational education is concerned with such matters as the exchange of teachers, students, and educational materials, technical assistance to other countries, and educational research and conferences on an international scale. It embraces the subject of "comparative education," which is the comparative study of educational theories and practices in different countries. It has recently acquired also the connotation of broadening the curriculum so as to introduce the student to men of all parts of the world. More narrowly, the term is applied to international educational programs, carried out by governmental and non-governmental agencies, for the purpose of promoting understanding and amity among nations.

Development between 1900 and 1939.—During the 19th century an international perspective in education had developed. The pace quickened between 1900 and 1940 with the establishment of international scholarships, arrangements for the exchange of students and teachers, and the founding of organizations aimed at promoting study abroad. Perhaps the best known of the scholarships was that named after Cecil J. Rhodes (1853–1902), the British financier and administrator in South Africa. He left a major share of his vast fortune for the establishment of perpetual scholarships at Oxford University to be held by students from the larger British colonies and the United States. See also RHODES SCHOLARSHIPS.

A foundation to finance a variety of educational activities in China and the United States was established in 1925, the China Foundation for the Promotion of Education and Culture. The League of Nations entered the field of international education when the Council of the League established a Committee on Intellectual Cooperation, to promote the circulation of intellectual works between nations.

The Institute of International Education, a private nonprofit organization, was founded in 1919 by Stephen Duggan, Elihu Root, and Nicholas Murray Butler. It appealed to colleges and universities in the United States for scholarships to be offered to carefully chosen foreign students. The institute also asked the governments of other countries to offer scholarships to American college graduates for study in their universities, these being government institutions. Some foreign countries gladly matched the scholarships provided by American institutions. By the start of World War II in 1939, the institute had facilitated the exchange of approximately 5,000 students on scholarships between institutions of higher education in the United States and other countries. Following World War II it greatly expanded its activities, working largely under formal agreements with the United States Department of State.

The Bureau International d'Éducation was founded in Geneva in 1925 to aid the cause of international education by conducting research, providing information, and holding international conferences. The Institut Universitaire de Hautes Etudes Internationales was also established in Geneva in 1927 by the Swiss cantons with the assistance of the Laura Spelman Rockefeller Memorial. Affiliated with the University of Geneva, it aims to promote international solidarity, and is a center of study for contemporary international questions of legal, economic, social, and political importance.

In 1934 the government-supported British Council was established to promote greater

knowledge abroad of the United Kingdom and of the English language. It encourages the teaching of English and of British studies in foreign countries, and through books, magazines, lectures, and cultural activities it fosters wider understanding of British life and customs.

The United States government became increasingly involved in international education after the middle of the 19th century. Congress in 1896 assigned the United States Office of Education the statutory responsibility of carrying out and publishing studies of education in other countries. In 1906 the United States became a participant, through membership, in the Pan American Union's educational program. In 1936 it acceded to the Buenos Aires Cultural Convention, with its provisions for the exchange of students and teachers.

The Immediate Postwar Period.—At the close of the war the nations of the West were immediately confronted by two major problems in international education: (1) the reconstruction of the educational systems of the war-devastated countries; and (2) the education of the defeated nations in the ways of democracy.

The Commission for International Educational Reconstruction, established in 1946, grew out of a series of conferences called by the American Council on Education to consider the critical problems of education in the war-devastated countries. The commission endeavored to stimulate and coordinate American voluntary efforts on behalf of education in the war-torn lands. Before the close of World War II, interested agencies of the United States and certain allied countries cooperated in formulating policies for the reeducation of the Axis nations. These policies called for the suppression of highly nationalistic teaching and the furtherance of instruction in democratic ideals.

From 1945 to the Present.—*International Agencies.*—An important step in the development of international education was taken when the United Nations Educational, Scientific, and Cultural Organization (UNESCO, q.v.) came into being in 1946. Its charter provides for (1) collaboration in the advancement of mutual understanding of peoples; (2) encouragement of popular education and the spread of culture; and (3) increase and diffusion of knowledge. The activities of UNESCO have grown in scope and significance since 1946. In recent years UNESCO has emphasized international projects for the reduction of adult illiteracy and for "fundamental education," which refers to the minimum of education required to combat the interrelated problems of illiteracy, ill health, undernourishment, and low productivity confronting the world's underdeveloped regions. It has also instituted programs in Latin America, Asia, and Africa for the expansion of primary education. Other UNESCO activities have included: general cultural projects; scientific problems of international scope, such as arid zone climatology; and encouragement of international travel and exchange student programs.

Another development following World War II was the establishment of the Institute for International Educational Research at Frankfurt, Germany. Under the sponsorship of UNESCO and the American Educational Research Association the first international conference on educational research was held at Atlantic City, N.J., in February 1956.

The Food and Agricultural Organization of the United Nations (FAO, q.v.) provides fellowships for senior technical personnel working in the fields of agriculture, forestry, home economics, and related subjects. The World Health Organization (WHO, q.v.), a specialized agency of the U.N., has an elaborate program for the promotion of health education, involving fellowships and arrangements with colleges and universities in many countries.

United States Government Programs.—After World War II three important congressional acts gave a new impetus to international exchanges in education. The Fulbright Act of 1946 provided that some of the currencies and credits of other countries acquired by the United States through the sale of surplus property abroad might be used for educational exchanges. Mature scholars, as well as younger students, have been able to enjoy the benefits of foreign study under this act, which was supplemented by the Smith-Mundt Act of 1948 and the Mutual Educational and Cultural Exchange Act of 1961. The Institute of International Education cooperates with the Department of State in the administration of these and other special government exchange programs.

The international education exchange program was born of faith in the American way of life and conviction that exchanges with other free nations lead to mutual understanding and respect. Through this program the United States government has sought to strengthen the security of the free world, in a climate unhealthy to dictatorship and nourishing to the growth of democracy.

The Agency for International Development (AID) was established in 1961 as an agency within the Department of State. One of its functions is to assist less developed countries to promote economic development, with emphasis on education through programs of technical cooperation. Much of the training given under the program is the responsibility of American and foreign colleges and universities, which administer certain aspects of the program under contract with AID. A number of foreign educational institutions and systems receive direct support from AID. The overseas information program of the United States Information Agency (USIA) is also involved in international education, for it is intimately connected with the curricula and activities of universities abroad. Often an affiliation between an American and a foreign university has been facilitated by the USIA.

The Peace Corps, established in 1961 as an agency within the Department of State, provides skilled manpower to newly developing nations. Peace Corps volunteers teach or perform other assigned duties in the communities to which they are sent.

Several constituent agencies in the Department of Health, Education, and Welfare administer programs in the field of international education. Some of these activities are carried out under agreements with AID or the Bureau of Educational and Cultural Affairs within the Department of State. The programs of the Office of Education include such activities as teacher exchange between the United States and other countries, and research and dissemination of information abroad. The Office of Education contains a Bureau of International Education consisting of a Division of International Studies

and Services and a Division of Technical Assistance and Exchange Programs.

Nongovernmental Programs in the United States.—Privately supported educational institutions, foundations, religious organizations, and other nongovernmental agencies provide schools and universities, books and libraries, welfare services, hospitals, and thousands of well-trained American personnel for humanitarian, scientific, and academic services abroad. Hundreds are sending materials and information abroad, exchanging persons, and carrying on other types of projects important to the task of promoting international understanding.

American foundations play an increasingly important role in the educational relations of the United States with foreign countries. The foundations administer large funds and often set the pattern for the programs of other private organizations. Ford Foundation fellowship grants have provided opportunities for American scholars to study in all parts of the world.

Although practically throughout their history American religious organizations have been active in other countries, since World War II the significance of their activities has grown in relation to the goals of international education. While endeavoring to spread Christianity in non-Christian countries, Protestant and Catholic churches have been active in the establishment of schools, colleges, hospitals, and other centers that have contributed to the advancement of education. American Jewish organizations have joined the Christian churches in the development of educational facilities abroad.

Other American nongovernmental organizations now active in the field of international education include professional and service organizations such as the American Council of Learned Societies, several commissions and committees of the American Council on Education, the American Library Association, the Institute of International Education, the National Academy of Sciences, the National Education Association, and the Social Science Research Council.

INTERNATIONAL EXCHANGE. See BANKS AND FINANCE—17. *World Trade and World Finance* (Foreign Exchange).

INTERNATIONAL FALLS, city, Minnesota, county seat of Koochiching County, situated 165 miles northwest of Duluth. The city is located on the south bank of the Rainy River, which here forms the American-Canadian international boundary. A bridge connects it with Fort Frances, Ont. A port of entry, it has a customs house and is a station of the United States International Border Patrol. International Falls is the center of a truck-farming and dairying region,

producing clover, alfalfa seed, potatoes, and vegetables. Manufactures include newsprint, paper products, insulite, and butter. Founded in 1881 by Alexander Baker, it was incorporated as a village in 1901 and as a city in 1910. It is governed by mayor and council. Pop. 6,778

INTERNATIONAL GEOPHYSICAL YEAR (IGY). The International Geophysical Year was the third in a series of "International Years" devoted to a study of the physics of the earth. Its predecessors, the First International Polar Year of 1882-1883 and the Second International Polar Year of 1932-1933, were concerned primarily with the Arctic; the IGY emphasized the entire globe.

The IGY covered a time period of 18 months (July 1, 1957 to Dec. 31, 1958), which was chosen to coincide with a maximum of solar activity. The study, in the 11 scientific fields of geophysics, constituted the most extensive examination of the planet earth yet made—from its deep interior outward into interplanetary space. To carry out the endeavor, over 4,000 geophysical stations, 80 oceanic research vessels, and 10,000 scientists were involved.

The IGY was administered under the auspices of the International Council of Scientific Unions (ICSU), which established a Comité Spécial de l'Anne Geophysique International (CSAGI) to supervise and integrate the effort. In addition to instituting a comprehensive program of geophysical observations, the IGY evoked a spirit of cooperation among the 66¹ participating nations that is unique in international relationships.

Although the IGY officially terminated on Dec. 31, 1958, the enterprise continued on a more limited scale as International Geophysical Cooperation 1959 (IGC-59). The success of the IGY prompted ICSU to create several new committees to coordinate future research: Committee on Space Research (COSPAR); Special Committee on Antarctic Research (SCAR); Special Committee for Oceanic Research (SCOR); and International Geophysical Committee (CIG). Also, a "little IGY" has been proposed for 1964-1965, during the next period of minimum solar activity.

The broad objective of the IGY was a more complete knowledge of the characteristics of the earth and its environs. To meet this goal, it was necessary to obtain simultaneous measurements, from many places on earth, of the weather, ocean conditions, the aurora, the ionosphere, the earth's magnetic field, etc. The observations not only provided an instantaneous picture of, for example, weather or the ionosphere over the

globe, but also will serve as a basis for detecting long term changes in slowly varying phenomena (for example, glacial mass, carbon dioxide content of the atmosphere, temperature of the earth). To study solar influences on the earth, an alerting system was established to notify participating countries that certain observations should be intensified. The "alerts" were issued whenever the Boulder, Colo., analysis center believed that changes in the upper atmosphere could be caused by a solar flare or other active solar conditions.

The tremendous quantities of data amassed by the IGY were deposited in three World Data Centers. Data Center A is located in the United States, B in the USSR, and C is divided among western Europe, Australia, and Japan. Each center will store a complete set of the IGY observations, and will make these data and working space available to researchers.

Some broad results of the IGY are: (1) the promotion of greater scientific cooperation among scientists and nations; (2) the erosion of specialization and the consequent cross fertilization of the geophysical sciences; (3) the large scale use of cosmic rays as a geophysical tool; and (4) clarification of terrestrial events following certain solar flares. The IGY stimulated geophysics, fostered a well planned scientific invasion of Antarctica, and advanced the responsible scientific exploration of space.

Under the aegis of IGY and IGC-59, many technological "firsts" took place: launching of an artificial satellite (Sputnik I, Oct. 4, 1957); compilation of complete Antarctic weather maps; launching of lunar and space probes; transarctic submarine passage via the North Pole (*Nautilus*, Aug. 3, 1958); modification of outer space by a nuclear detonation (Project Argus, Aug. 30-Sept. 3, 1958); rocket observations during a solar eclipse (Danger Islands, Oct. 12, 1958); attainment of the moon by an unmanned rocket (Lunik II, Sept. 13, 1959) and photographs of the unknown face of the moon (Lunik III, Oct. 5, 1959).

Satellites and Space Probes.—Satellite vehicles of various sizes and complexity were orbited by the United States and the USSR. The scientific successes of the early satellites led to direct probings in the vicinity of the moon and in interplanetary space at great distances from the earth.

The satellites and space probes provided information on the temperature and density of the upper atmosphere, the charged particle concentrations above the ionosphere, the meteor density in space around the earth, the rate of decrease of the earth's magnetic field, the intensity of cosmic radiation, etc. They also allowed the discovery of the crescent-shaped radiation zones encircling the earth and roughly pointing at the geomagnetic poles (Van Allen radiation belts, q.v.). These belts contain ionized particles of rather high energy and constitute a region of intense radiation whose maximum is found over the geomagnetic equator.

Observations on the deceleration of artificial satellites indicated that the mean value of atmospheric density at altitudes above 225 kilometers (km.) is about 10 times greater than previously estimated. The density of the outer atmosphere seems to be half as large in June as in December. The cause may, perhaps, be traced to the difference in positions of the earth in its orbit. Electron concentrations above the maxi-

¹The 66 participating nations were: Argentina, Australia, Austria, Belgium, Bolivia, Brazil, Bulgaria, Burma, Canada, Ceylon, Chile, China (Taipei), Colombia, Cuba, Czechoslovakia, Denmark, Dominican Republic, East Africa, Ecuador, Egypt, Ethiopia, Finland, France, German Democratic Republic, German Federal Republic, Ghana, Greece, Guatemala, Hungary, Iceland, India, Indonesia, Iran, Ireland, Israel, Italy, Japan, Korean Democratic Republic, Malaysia, Mexico, Mongolian Peoples Republic, Monaco, Netherlands, New Zealand, Norway, Pakistan, Panama, Peru, Philippines, Poland, Portugal, Rhodesia and Nyasaland, Rumania, Spain, Sweden, Switzerland, Tunisia, Union of South Africa, United Kingdom, USSR, United States, Uruguay, Venezuela, Vietnam Democratic Republic, Vietnam Republic, and Yugoslavia.

Although China (Peiping) withdrew from the IGY in protest at the inclusion of China (Taipei), a large geophysical program was instituted. The meteorological network was expanded from 50 to 1,500 stations; geophysical observatories were established at Lanchow, China, and Lhasa, Tibet, and research in many geophysical fields, including oceanography, undertaken.

mum of the F ionic layer were found to decrease about six times more slowly than the increase from the bottom of the ionosphere to the F layer maximum at 300 km. At 1,000 km., the atmospheric number density is about 7×10^{10} per cm.³

Several hundred ions per cm.³ surround the earth from high in the atmosphere to about 14,000 miles after which the density drops. This highly rarified outer atmospheric "geo-corona" is probably hydrogen, and probably originated in water evaporated from the oceans and subsequently dissociated high in the atmosphere by sunlight.

Deductions from satellite measurements revealed that the earth is very slightly pear shaped (with the stem end near the North Pole), and that it does not bulge at the equator to the extent hitherto expected. The moon probe, Lunik III, showed that the moon possesses a weak magnetic field, if any, and is not enveloped by radiation belts as is the earth. Ion concentrations increased within some 10,000 km. from the moon. Photographs of the hitherto unseen side of the moon (made 37,000 to 41,000 miles above the surface) showed that only about 10 per cent of the far side is covered with "seas" as compared with 30 to 35 per cent of the known side.

Antarctica.—Twelve nations sponsored major scientific expeditions to Antarctica. Discoveries included new mountains, mountain ranges, coal and mineral deposits. From an analysis of seismic waves, Antarctica was found to be mainly continental in character; however, the ice sheet also caps a number of islands. Many long distance surveys making seismic soundings and gravity measurements were completed.

Bore holes were drilled at Little America (850 feet), Byrd (1,400 feet), and Mirny. The international Antarctic Weather Central made detailed analyses of Antarctic meteorology and supplied weather forecasts to all parties. The continent was found to possess 40 per cent more ice than previously assumed. Large volumes of ice extend to the bottom of the sea. Near Byrd, for example, ice 14,000 feet thick lies on bedrock 8,200 feet below sea level. This ice may be the thickest yet measured anywhere. The lowest temperature on earth, -125.3°F. , was registered near the center of Antarctica. Nonflowering plants (algae, lichens, and mosses) were found to have a remarkably wide distribution throughout the ice-free areas.

Arctic.—Four drifting stations were established (A and B by the United States and SP6 and SP7 by the USSR) on the floating ice of the ocean. Stations C and SP8 replaced A and SP7 after they were closed by ice degeneration. Measurements from the floating observatories supplemented those from the fixed land stations, and provided information on ocean bottom topography, water movements, water-ice heat budget, net increase of ice, etc. In addition, data were obtained on the state of the ionosphere, aurora, magnetic field, etc.

Rocks of all shapes and sizes, abundantly scattered about the bottom, appeared to be a general feature of the Arctic Ocean. Little life was found on the ocean floor. However, sponge, shrimp, fish and sea anemone were photographed on a newly discovered underwater plateau about 8,000 feet above the ocean floor.

General.—New ocean currents were found. A counter Gulf stream was located in the Atlantic. In the Pacific, two great currents were mapped:

the equatorial undercurrent and the countercurrent. The undercurrent, larger than the Gulf Stream in volume, is 3,500 miles long, 250 miles wide, lies at a depth between 100-800 feet; flows eastward and disappears near the Galapagos. Of 89 Swiss glaciers studied, 83 receded an average of 48 feet during the IGY—one indication in support of the thesis that the earth is now slowly warming up.

Some displays of the aurorae borealis and australis occurred at the same time. The presence of the equatorial electrojet (an electric current flowing in the atmosphere above 100 km.) was confirmed, as predicted by theory. A new atomic emission at 6700 Å, attributed to lithium generated during nuclear explosions, was detected in twilight spectra.

The most brilliant solar flares that also emitted a characteristic radio noise were found to initiate by three events on earth: (1) a proton shower one to five hours later; (2) a magnetic storm, one to two days later; and (3) a sudden decrease in cosmic ray intensity at or just before the time of the magnetic storm. The most important solar emission lines seem to be those of hydrogen (Lyman alpha, 1216 Å) and helium (singly ionized, 304 Å). Both far outshine all other solar ultraviolet emissions.

N. C. GERSON,
Former Secretary, United States National Committee for the IGY.

INTERNATIONAL LABOR ORGANIZATION (ILO), an intergovernmental agency of 78 member nations, established in 1919 at the Paris Peace Conference and in 1946 made a specialized agency of the United Nations. The United States joined in 1934.

Organization.—Workers, employers, and governments share in making its decisions and policies, in which respect the organization is unique among international agencies. Each national delegation has four members, one each for the workers and employers and two for the respective governments; each delegate has one vote in the annual conference and other meetings of the organization. This tripartite structure gives the ILO its balance and much of its strength.

The chief purpose of the ILO is to improve-labor conditions and raise living standards. Operating from headquarters in Geneva, Switzerland, and through various branch and field offices scattered throughout the world, it functions through three principal organs: (1) an International Labor Conference, the supreme body of the organization which provides a world forum for labor and social questions; (2) a governing body, the executive council, which is composed of 20 government, 10 management, and 10 labor representatives; and (3) an International Labor Office, the secretariat, which serves as an operational headquarters, a world information center, and a publishing house. In 1957, the chief executive officer was the director general, David A. Morse, who was a former United States undersecretary of labor.

Program.—Since mid-20th century, the ILO has emphasized its operational programs such as technical assistance. Through the combined funds provided under its regular budget and through the United Nations Expanded Technical Assistance Program, the ILO provides governments with expert advice and technical assistance in matters connected with labor and social policy.

By the end of 1956, it had sent more than 650 technical assistance experts to Asia, Latin America, Africa, the Middle East, and elsewhere, helping less developed countries with the many problems of industrial and agricultural expansion.

Field offices have been established in various parts of the world to serve as centers for assistance to governments in such matters as vocational training, increasing productivity, building up employment services, and encouraging the development of handicrafts and cooperatives. In addition, the ILO has awarded more than 1,375 fellowships and study grants to underdeveloped countries and placed more than 800 workers and foremen for practical on-the-job training in factories abroad.

A major project of the organization is the eradication of forced labor from the world. In 1957, a convention with this aim was in the process of adoption following concentrated study by an *ad hoc* committee appointed to uncover this social evil imperiling freedom of association and the individual liberties of workers.

Work is also being done to improve labor-management relations throughout the world. Increased attention is being given to the economic and social effects of automation, the industrial use of atomic energy, and discrimination in employment.

Through research and investigation, the ILO continues to assemble current information concerning the world labor market and the various important developments which can provide the basis for better working and living conditions of the world's population.

Since 1945, the ILO has established eight industrial committees to aid in solving the social and economic problems peculiar to particular industries. These are now organized for coal mining, textiles, construction, iron and steel, the metal trades, inland transport, petroleum production and refining, and the chemical industry. A large number of commissions and committees have also been set up to study occupational health and safety, the employment of women, social security, and the problems of white collar workers.

Standards.—In the years since its organization, the ILO, through the adoption of more than 100 conventions and numerous recommendations, has written an International Labor Code. This code of conventions and recommendations deals with unemployment, weekly rest periods, maternity protection, maritime working conditions, the right of workers to organize, and the right to bargain collectively, among many others.

Member countries agree to examine each convention for possible ratification and to report to the ILO from time to time concerning the state of local law and practice. Thus, ILO conventions influence standards even in countries where they have not been ratified. Recommendations do not require ratification.

Through all its various programs, the ILO aims at putting peace on a solid base of social justice. Its motto is: "Poverty anywhere is danger to prosperity everywhere." See also CHILD LABOR—*International Movements for Regulation*; COLLECTIVE BARGAINING—*International Aspect*.

RICHARD W. BALENTINE,
International Labor Office, Washington, D.C.

INTERNATIONAL LANGUAGE. See UNIVERSAL LANGUAGE.

INTERNATIONAL LAW, a term usually defined as that body of rules, principles, and standards to which independent states are bound by common consent. This definition assumes that the source of international law is the consent of those bound and that its sanction is good faith.

SOURCES AND SANCTIONS

The lack of coercive sanctions has induced some writers to assume that international law has the character of morality rather than of law. There are, however, other sanctions and other sources of international law. Thus, in addition to the sanctions of good faith, of foreign office habituation, of national self-interest, and of world opinion, international law is sanctioned by the probability of retaliatory action by the state injured by its violation and, in recent times, by the activity of international agencies in organizing positive sanctions in case of serious violations. The effectiveness of these sanctions has varied during the past five centuries, according to the stability of the balance of power, the efficiency of international organization, and the adaptation of international law to changing conditions. The interests of states have been influenced by the progress of technology and the development of new ideologies, by the rise of new nations and the disintegration of empires, by the political and industrial revolutions, and by the increase of economic and political interdependencies among states. International law has often lagged behind changes in the interests which it seeks to protect resulting from such new conditions.

Even under the most favorable conditions, the sanctions of international law have been less reliable than the procedures and forces usually available to national governments to apply and enforce the law of the state. In recent times, in spite of the improvements in "international organization" and the abundance of "international legislation," the rapidity of technical, social, political, and economic change has been such that changes in international law have not kept pace. The reliability of international law can be increased both by legislative procedures to keep it up to date and by judicial and executive procedures to apply and enforce it in particular cases. Because of the accepted principle that a state cannot be bound by a new rule of international law without its consent, the problem of developing adequate legislative procedures in a rapidly changing world presents great difficulty—a difficulty not entirely obviated by the greatly improved procedures which have been developed during the past years.

The sources of international law are also broader than expressed consent. Thus the Statute of the International Court of Justice provides as follows:

The court, whose function is to decide in accordance with international law such disputes as are submitted to it, shall apply:

- (a) international conventions, whether general or particular, establishing rules expressly recognized by the contesting states;
- (b) international custom, as evidence of a general practice accepted as law;
- (c) the general principles of law recognized by civilized nations;
- (d) subject to the provisions of Article 59, judicial decisions and the teachings of the most highly qualified publicists of the various nations, as subsidiary means for the determination of rules of law.

Article 59 declares that "the decision of the court has no binding force except between the

parties and in respect to that particular case." In a broad sense the four sources resemble those of national law systems, usually summarized as agreement, custom, reason, and authority; however, the authority of judges and publicists to make and interpret law for the community of nations is very different from the authority of legislative bodies and courts to make and declare law within modern states.

International law, therefore, differs considerably in both its sanctions and its sources from systems of national law, but the difference is one of degree rather than of kind. International law has been observed by the states subject to it and applied by their courts in suitable cases, except when an emergency situation or a new condition has convinced the government that observance would adversely affect a vital national interest. Such situations and conditions have, however, been frequent in the 20th century. A system of law is effective in proportion to the solidarity and integration of the society in which it functions. Since the society of nations is highly decentralized and incoherent, international law has been imperfectly effective and will remain so until individuals and governments identify themselves and their interests with that society in greater degree, permitting a greater centralization of international institutions.

HISTORICAL SURVEY

In a broad sense international law has existed whenever independent political groups have come into regular contact with one another. Thus, most primitive peoples recognize rules applicable in their relations with neighboring tribes. The ancient Greek city-states, the Mediterranean states of the Hellenistic period, the states of Confucian China, and the states of ancient India, each constituted a "society of nations" which recognized many rules regulating the intercourse of the members. In the Middle Ages, princes, nominally subject to feudal superiors, pyramiding up to the emperor and the papacy, increasingly accepted practices concerning diplomatic representation, maritime commerce, treaty interpretation, and war. Philosophical discussions distinguished just from unjust war, and recognized limitations upon the waging of war, some of them learned by Christendom from the Saracens during the Crusades.

Origin of Modern Concepts.—It was not, however, until the breakup of the medieval system and general acceptance of the concept of territorial sovereignty in the 15th century that international law began to assume a systematic character. The speculations of medieval theologians and philosophers, the practices of the Italian states in the late Middle Ages, the writings of Renaissance political scientists like Niccolò Machiavelli and Jean Bodin, the practices of contemporary sovereigns, and particularly the classical concept of "natural law" were drawn on by a body of writers whose works have been translated and published in recent years by the Carnegie Endowment for International Peace under the title *The Classics of International Law*. These writers of the 16th, 17th, and 18th centuries are divided into three schools—the naturalists, who emphasized the moral and rational principles of "natural law," the positivists who emphasized custom and agreements, and the eclectics who gave weight to both, as does the Statute of the International Court of Justice.

Among the naturalists were members of the 16th century Spanish school, Francisco de Vitoria (1480?-1546) and Francisco Suarez (1548-1617), and the 17th century German, Baron Samuel von Pufendorf (1632-1694). Vitoria's treatises were compiled from lectures which he gave at the University of Salamanca in 1532, inspired by the recent conquest of Mexico by Hernán Cortés. He inquired into the right of the Spanish sovereigns to conquer princes of the New World, and was thus led to set forth a system of rules based upon "natural law" which alone, he thought, could govern the relations of sovereigns of widely different culture and religion. Pufendorf was influenced by the British political philosopher, Thomas Hobbes, who taught that man in a "state of nature" is bound only by the "natural right" of self preservation, and that the absence of a sovereign authority to enforce law led to a state of war of all against all. He considered sovereign princes to be in this situation, although reason would urge acceptance of rules of "natural law" such as the observance of agreements, and the establishment of authority to enforce them. Pufendorf was more optimistic about the nature of princes, and felt that reason, embodied in natural law, would be in a measure self-executing.

Among positivists were the Italian jurist, Alberico Gentili (1552-1608), who became an adviser of Queen Elizabeth I; the English judge, Richard Zouche (1590-1661); the Dutch judge, Cornelis van Bynkershoek (1673-1743), who is distinguished for proposing the three-mile limit for a state's territorial waters; and the German jurist, Johann Jakob Moser (1701-1785).

The leading eclectic was Hugo Grotius (q.v.), a Dutch jurist, theologian, and philosopher, often called the father of international law. His famous treatise on *The Law of War and Peace* appeared in 1625, during the early part of the Thirty Years' War and was in part inspired by the desire to mitigate the barbarities of that war. The philosopher, Baron Christian von Wolff (1679-1754) and Emmerich Vattel (1714-1767) wrote in the mid-18th century, the first emphasizing the great society, or *Civitas Maxima*, as the source of authority for international law, and the latter the balance of power as the condition which sanctioned it. While often called eclectics, these two writers should, perhaps, be classed with the naturalists because, in principle, they deduced international law from reason, which taught, according to Vattel, that agreements, whether expressed, tacit, or implied, should be observed. These classical treatises were all in Latin except that of Vattel, who wrote excellent French—perhaps accounting for the very wide publicity given to his treatise particularly among the constitutional founders of the United States. The leading American international lawyer of the 19th century, Henry Wheaton (q.v.), based his treatise in large measure upon Vattel.

In the 19th century a very large number of writers in all languages wrote on international law largely from the eclectic or positivist point of view. Among naturalists the outstanding writer in the English language was the Scot, Sir James Lorimer (1818-1890), whose treatise appeared in the 1880's. The best known recent treatises in English are those by Lassa Oppenheim (1858-1919), late professor at Cambridge University, and Charles Cheney Hyde (1873-1952), late professor at Columbia University. In

recent times, rapidly changing conditions have led international jurists to explore basic principles of psychology, sociology, and politics, as well as of ethics, to discover the rules and principles best adapted to the emerging situation, thus reviving the idea of natural law, but with a more evolutionary connotation than was attributed to that term by the classicists. The emergence of this school has led to a distinction between "the new international law," which emphasizes principles based upon the values expressed in general treatises and declarations and the practical requirements of the situation, and "traditional international law," which accepts only concrete rules established by custom (especially those established before World War I) or by formally ratified treaties. Advocates of both points of view seek to formulate the law in general statements equally and reciprocally binding on all parties to a controversy.

Periods of Development.—The history of modern international law can be conveniently divided into five periods separated from one another by great wars. The first period, from the discovery of America and the development of powerful monarchies in Spain, France, and Britain in the late 15th century to the Peace of Westphalia (1648) ending the Thirty Years' War, was characterized by the establishment of territorial sovereignty as the basic principle of international relations. The wars of religion, precipitated by the Reformation early in the 16th century, were ended by acceptance of the formula *cuius regia eius religio*. It was recognized that each secular prince could determine the religious problems within his domain. During this period, the classical writers of international law established doctrines, often based on principles of Roman law identified with "natural law," concerning acquisition of territory, demarcation of boundaries, diplomatic privileges and immunities, rules concerning treaty negotiation and interpretation, and principles concerning the initiation and conduct of war.

The second period extended from the Peace of Westphalia (1648) to the Peace of Utrecht (1713), ending the War of the Spanish Succession, and was characterized by recognition of the balance of power as the principle of European politics and the condition of a reliable international law. This principle was relied upon by England to justify its intervention in the wars of Louis XIV and was later defined by Talleyrand as "a combination of the mutual rights and interests of the powers, by means of which, Europe aims at securing the following objects: (1) that no single power, nor any union of powers shall have mastery in Europe; (2) that no single power nor union of powers shall be able to infringe the actual possession and recognized rights of any other power; (3) that it shall no longer be necessary, in order to maintain the established state of affairs, to live in a state of imminent or actual war, and that the proposed combination shall secure the peace and repose of Europe against the efforts of a disturber by diminishing his chances of success." During this period, the European states engaged in much overseas exploration and settlement, testing principles concerning territorial acquisition and establishing the freedom of the seas beyond territorial waters. Many treaties were made recognizing neutral rights of commerce in time of war.

The third period from the Treaty of Utrecht

to the Treaty of Vienna (1815), ending the Napoleonic Wars, was characterized by a great deal of naval war for trade routes and overseas territory, and the rise of nationalism and democracy in the American and French revolutions. As a result of the revolutionary ideologies, the concept of the state changed from the domain of an absolute monarch to a corporate body governing itself within a territory. The law of maritime war and the rights and duties of neutral states were developed during this period. International law in these matters was given a new precision through treaties, the judgments of prize tribunals, the judicial enforcement of neutral obligations, and the judicial recognition of diplomatic immunities. Ideas of international organization developed during the period through theoretical writings and were given limited application in practice through the system of guarantees and conferences set up by the treaties ending the Napoleonic Wars. In the latter part of the period, certain diplomatic, economic, and social problems such as the ranking of diplomatic representatives, the navigation of international rivers and straits, and the elimination of the slave trade were dealt with by general treaties, thus initiating the modern era of "international legislation."

The fourth period, from the Treaty of Vienna to the Treaty of Versailles (1919), was distinguished by the Industrial Revolution; great increases in wealth and population, especially in Europe and America; the shrinking of the world through new means of transportation and communication; and, under the dominance of British sea power and finance—the *pax Britannica*—the least war in Europe since the *pax Romana* of the 2d century A.D. It was marked by the great development of diplomatic and consular systems, by the extensive use of arbitration to settle international disputes, by the rise of nationality as a political principle, and by the operation of the "concert of Europe" to maintain an equilibrium of power and to deal collectively with political problems such as those faced in the disintegration of the Turkish Empire, the weakness of China, and the partition of Africa. The development of the United States and Japan as great powers outside of Europe; the recognition of Latin American, Asiatic, and African states as members of the society of nations; and the development of international unions and international legislation made the society of nations worldwide and strengthened its political and administrative organization. The international unions dealt with postal, telegraphic, and radio communications; with railroads and river and oceanic transportation; with commerce, migration, and health; and with problems of slavery, narcotic drugs, and war.

Particularly notable for international law during this period was the codification of basic principles of maritime international law in the Declaration of Paris (1856) and the unratified Declaration of London (1909). The codification of the law of land warfare was initiated in Francis Lieber's *Code for the Government of Armies* (1863), which was issued for the Union armies during the American Civil War, the most serious war of the period in the West. It was carried on internationally in the Geneva Red Cross Convention (1864), the Declaration of St. Petersburg (1868), and The Hague Conventions (1899, 1907). The latter included conventions on both land and maritime war and began to deal with aerial war by a declaration prohibiting the drop-

ping of explosives from balloons or aircraft. Declarations and conventions also dealt with gas warfare, the use of submarine mines, and naval bombardment. These extensive and, for the most part, widely ratified codifications defined the rights and duties of belligerents and neutrals with considerable precision and were generally observed during World War I.

Increasingly, as invention produced weapons of great striking power and mobility, jurists gave attention to the problem of eliminating or decreasing the probability of war through methods of pacific settlement. Arbitration, which had been used by the ancient Greeks and in the Middle Ages, was re-established by the Jay Treaty between Great Britain and the United States (1794), and some 400 international arbitrations were held during this period, notably the Alabama (1871) and Bering Sea (1894) arbitrations between the United States and Great Britain. Treaties for the future submission of disputes to arbitration were made and The Hague Conferences produced the Convention for the Pacific Settlement of International Disputes, which recognized the interest of third states in preventing hostilities, urged that they tender good offices to this end, provided for mediation and commissions of inquiry, set forth a code of arbitral procedure, and urged conclusion of treaties obliging the parties to arbitrate justiciable disputes. This convention also established a panel of arbitrators with administrative headquarters at The Hague, known as the Permanent Court of Arbitration. Several disputes were settled by recourse to this court and, at the Second Hague Conference, a Court of Arbitral Justice and an International Prize Court were proposed as permanently sitting tribunals. This effort was not realized until after World War I, but the Central American Court of Justice with jurisdiction over the five Central American republics was established in 1907 as the first genuine international tribunal of modern times.

In spite of the development of international law and the rise of pacific settlement during this period, it was clear that the balance of power was becoming less stable and that the destructiveness of weapons was making war more serious. The czar's prime purpose in calling The First Hague Conference was to reduce the prospects of war by disarmament and pacific settlement. No progress was made in disarmament nor was arbitration made obligatory, and the bipolarization of power through the development of two great alliance systems in Europe at the turn of the century augmented the arms race and led to World War I. Experience with the purely voluntary Hague system led, after that war, to the establishment of the League of Nations designed to put teeth in that system by preventing or stifling aggression, assuring pacific settlement, and establishing international law, through collective action of the members.

The fifth period, beginning after the Treaty of Versailles, is covered below, under the section *International Law Since World War I*.

INTERNATIONAL LAW SINCE WORLD WAR I

The final period in the history of international law from the Treaty of Versailles to the present time has been characterized by the functioning of the League of Nations and the United Nations; by acceleration in the breakup of empires and the self-determination of nations; by the rise

in importance of Asiatic and African states in international politics; and by the accelerated utilization of aviation, electrical communication, and nuclear energy—thereby shrinking the world, rendering all states vulnerable to sudden attack, and increasing the destructiveness of war. The period has also witnessed an extraordinary increase in international legislation and administration to serve economic, social, and humanitarian interests, and the emergence of the human rights of individuals and the self-determination of nations as basic interests of the world community. The consolidation of the society of nations founded upon international law stimulated the emergence (among those dissatisfied with the status quo) of opposing aggressive ideologies of fascism, nazism, and communism challenging the ideology of democratic, humanistic nationalism. This challenge resulted in World War II, in which democracy allied itself with communism to exterminate fascism and nazism. This was followed by the cold war between democracy, led by the United States, and communism, led by the Soviet Union. These events have led to reappraisals of international law from the points of view both of content and of enforcement with the hope of narrowing the gap between the asserted values and the actual practices of sovereign states.

The various factors influencing international relations during the past century have resulted, on the one hand, in the rise of nationalism, consequent upon more extended literacy, democracy, and centralization of national political and economic authority; and on the other hand, in the development of internationalism, consequent upon inventions which have expedited world communications, travel, and transport, increased international trade, and developed international organization. In 1894, the distinguished French publicist Henri Bonfils wrote: "Public international law proposes to reach a compromise between two actions contrary in fact, that of the principle of autonomy of states, and that of the notion of the cosmopolitan society. Neither of these two principles ought to supplant the other, nor to be put completely to its practical application." (*Manuel de droit international public*, section 24, p. 10, Paris 1894; 6th ed., Fauchille 1912.) These two tendencies have each been exaggerated by the factors referred to and as a result the task of international law in compromising them has become more difficult. That difficulty has been reflected in the rapid oscillation between wars of extreme violence and institutional constructions of extraordinary scope which have characterized international life since 1914.

Nationalism, nurtured in 19th century ideas of liberalism, was affected by protectionist pressures of business, by socialistic pressures of labor, by imperialistic pressures of politics, by militaristic necessities in waging war, and by the defensive urge to acquire invulnerability from blockades after World War I. As a result, nationalism developed among the politically less experienced people of Europe into fascism, nazism, or communism, creating totalitarian states with control of government, economy, religion, and opinion centralized in irresponsible dictators intent on continually expanding the sovereignty, self-sufficiency, military power, and living space of the national group. Nationalism of this form, equipped with such modern devices

as the airplane, the submarine, heavy mobile artillery, machine guns, conscription, propaganda, and controlled economy has given war a totalitarian character, regimenting the population and subjecting civilians to hardships unparalleled in history. Whether the hydrogen bomb will reinforce this tendency or—by the very magnitude of its threat—will revolutionize the world order, remains to be seen.

The totalitarian states in their early history avowed new concepts of international law. The conceptual repudiation of established international law by fascist, nazi, and communist governments tended to decline, in proportion as these governments entered into relations with others and were confronted with the need to solve international problems; however, in practice, these states manifested an extreme propensity to neglect the rules of international law. Other states have also departed from established law, partly in retaliation and partly in adapting themselves to changed technical conditions.

During World War I, certain weaknesses in international law were recognized, particularly (1) the lack of a legal interest of third states in the observance of international law when their own immediate interests were not involved; (2) the emphasis on international rights rather than international responsibilities; (3) the lack of a legal obligation of states to accept external judgments in their controversies; and (4) the lack of an international organization to represent the general interest in law observance, to provide for impartial adjudication of disputes, and to enforce responsibilities under international law. It was hoped that the peace ending World War I would remedy these deficiencies.

Thus, with respect to the legal interest of states, Elihu Root said in 1915: "If the law of nations is to be binding, if the decisions of tribunals charged with the application of that law to international controversies are to be respected, there must be a change in theory, and violations of the law of such character as to threaten the peace and order of the community of nations must be deemed to be a violation of the right of every civilized nation to have the law maintained and a legal injury to every nation. . . . Wherever in the world the laws which should protect the independence of nations, the inviolability of their territory, the lives and property of their citizens, are violated, all other nations have a right to protest against the breaking down of the law. Such a protest would not be an interference in the quarrels of others. It would be an assertion of the protesting nation's own right against the injury done to it by the destruction of the law upon which it relies for its peace and security." ("The Outlook for International Law," *Proceedings of the American Society of International Law*, 1915.)

With respect to international responsibilities the present writer wrote in 1919: "Thus, though international law must continue to aim at preserving the independence and autonomy of states, it must assume that its own preservation is more important. It follows that international law can no longer be conceived by text writers as a series of deductions from an assumed 'fundamental right of states to exist.' The responsibility of states to assure the existence of the law will have to be conceived as even more fundamental. . . . States cannot survive where sovereignty can override the law." ("Effects of the

League of Nations Covenant," *American Political Science Review*, November 1919.)

With respect to the right of self-judgment, and the need of international organization, John Bassett Moore wrote in 1915:

"If states do not succeed (in gaining redress for injuries by amicable modes) it is laid down that they may try inamiable methods, ranging all the way from retorsion to retaliation, embargo, commercial nonintercourse, severance of diplomatic relations, and display of force, to reprisals, which are acts of war, and to war itself, which is in its physical aspect merely general reprisals. Nevertheless, if actual force be employed, there is always the danger of forceful resistance, ending in war; and in that event we may have the incongruous result that the aggressor, without submitting to the examination of any tribunal the justice of his cause, may, in the exercise of the 'rights of war,' conquer or destroy the injured power which he has by his own wrong driven to become his adversary. This principle, which I conceive to be the capital defect of international law at the present day, is perhaps to be explained as the survival of the superstition that was preserved in municipal law for so many centuries, the process of trial by battle. However this may be, it is flagrantly at variance with all conceptions of human right, and can be effectually got rid of only through further organization. It is in this respect, as I have intimated, that international law differs from municipal law—not in its essence or its obligation, but in the method of its declaration and administration. Within the state we have an organization for the making, declaration and enforcement of law, whereas, as between nations, we are obliged to a great extent to rely upon their voluntary concurrence or cooperation. In other words, we lack in the international sphere that organization which gives to the administration of law within the state a certain security. This defect it is the business of nations to supply by forming among themselves an appropriate organization. The essential features of such an organization would be somewhat as follows: (1) it would set law above violence: by providing for the enforcement of law; and by making the use of force illegal, except in support of a duly ascertained legal right, or in self-defense . . . , (2) it would provide a more efficient means than now exists for the making and declaration of law . . . , (3) it would provide more fully than has heretofore been done for the investigation and determination of disputes by means of tribunals, possessing advisory or judicial powers, as the case might be Occasional disturbances such as these (domestic insurrections) should by no means lessen our estimate of the importance of organization for the maintenance of law, either international or internal. They should on the contrary serve to emphasize, not only the necessity of organization, but also the importance of extending its scope and increasing its efficiency." ("Law and Organization," *American Political Science Review*, February 1915.)

Changes in the Law of War.—The rules of war and neutrality, accepted by custom and by the great lawmaking conventions of the 19th and early 20th centuries, have been greatly modified in practice and perhaps in theory. Among such practices may be noted belligerent (1) internment of enemy civilians, (2) bombardments, (3) destruction of merchant vessels, (4) proclamation of war zones, (5) controls of neutral commerce, and (6) utilization of neutral territory. Neutrals have also resorted to new practices, such as, (7) renunciation of trading privileges, and (8) proclamation of peace zones on the high seas.

(1) While in the past, enemy civilians were sometimes expelled from belligerent territories, they were usually allowed to remain unmolested or given a period of grace in which to wind up their affairs and leave. Since World War I, however, enemy civilians have been interned and treated substantially as prisoners of war by most belligerents. Persons liable to military service have been taken from neutral vessels on the high seas and made prisoners of war. In short, civilians formerly of little military importance are now regarded as a military asset to their country, if not on the front line, then as workers in military production, and they have been treated accordingly by the enemy.

(2) Bombardments by land artillery were formerly confined to the armed forces or to defended towns, though in naval war the right of bombarding military objectives on land was recognized. Aviation has opened new fields to bombardment, and while in principle bombardment for terrorization of civilian populations is considered illegitimate, it occurred especially in the Spanish Civil War and in all theaters of World War II, culminating in the destruction of Hiroshima and Nagasaki by two atomic bombs. Bombardment of military objectives from the air was recognized as legitimate in the Draft Articles of 1923, prepared by experts in pursuance of a Washington conference resolution. Since railroad centers, docks, and factories in densely populated communities may come under this designation, since the aim of bombers, driven up several miles by anti-aircraft defenses, cannot be very accurate, and since the area of direct destruction and poisonous "fallout" of atomic bombs is large, the risk to civilians is very great, even if the law is observed. The threat of aerial bombardment has undoubtedly increased the diplomatic power of a government, suspected of ruthlessness and equipped with a considerable air force. With the increasing range, speed, and capacity of aircraft, the development of rockets, and augmentation of the power of bombs culminating in the hydrogen bomb, defenses against the bombing of civilians and industries in any part of the world have been reduced to the fear of retaliation.

(3) In the conduct of commercial warfare, the sinking of prizes has always been considered an exceptional act permitted only in case of necessity, after the passengers and crew have been placed in safety. The submarine, incapable of sparing prize crews and vulnerable to attack by defensive armaments on merchant vessels, has proved unable to engage in commercial warfare under these rules. An unratified convention of the Washington Conference of 1922 declared that, as a consequence, submarines could not engage in commercial war. Generally ratified provisions of the London Naval Treaties of 1930 and 1936 reiterated the old rule about safety of passengers and crew. Nevertheless, both belligerents, though parties to these conventions, engaged in submarine sinkings in the war of 1939-1945.

(4) The principle of freedom of the seas has meant for over two centuries that in time of war, merchant shipping is free to utilize all sea areas beyond territorial waters, subject only to acknowledged belligerent rights of visit and search, of capture for carriage of contraband, breach of blockade, unneutral service, or enemy character—subject since 1856 to the rule that free ships make free goods. In wars since 1914, however, belligerents mined vast areas of the sea and proclaimed zones where, on account of mines, submarines, or destroyers, navigation was unsafe. Though neutrals at first protested, they in a measure acquiesced in such actions and, in some cases, forbade their ships to enter zones deemed dangerous. Thus, the American Neutrality Act of 1939 authorized the president to proclaim barred zones, and under it he proclaimed the waters surrounding the British Isles, including the North Sea, such a zone. The act was repealed Nov. 17, 1941. A disposition to tolerate encroachments upon freedom of the seas has been manifested among jurists, as indicated by the Harvard Research in International Law, which permits a belligerent to establish blockade zones extending 50 miles

from the enemy's coast (Articles 1e, 69). After World War II the United States declared vast areas of the Pacific unsafe during atomic bomb tests.

(5) Belligerent extensions of contraband lists, broad applications of the rule of continuous voyage and ultimate destination, and resort to retaliatory measures rendering all trade, direct or indirect to or from the enemy, liable to capture have seriously impaired earlier neutral rights of trade even with other neutrals. But going beyond this, belligerents insisted on a deflection of neutral ships to ports for search and withheld bunker coal facilities from neutral vessels and blacklisted neutral firms, barring them from trade with the belligerent's nationals if they would not stop trading with the enemy. While neutrals at first protested, they have in a large measure acquiesced and, in some cases, have embargoed their own trade in certain commodities with belligerents. Jurists have manifested a certain tolerance for such practices. The Harvard Research in International Law suggested abandonment of the old rules in respect to contraband, and the substitution therefor of an elaborate system of certification of vessels with consent of the belligerents, all uncertified vessels being liable to a high degree of belligerent control (Articles 61, 63).

(6) The inviolability of neutral territory from belligerent operations has been a fundamental rule, although Japan and Russia fought their war in 1904 in Chinese territory. Germany began the war of 1914 with an invasion of neutralized Belgium. Russia in 1939 insisted on bases in Estonia, Latvia, and Finland, and when the latter resisted the demand, began military operations in Finnish territory. Belligerent airplanes frequently cruised over Dutch and Belgian territory before these states were attacked by Germany in 1940. Neutrals in the vicinity of belligerent operations lost all confidence that their territory would be respected.

(7) Aware that efforts to defend their trading rights might lead them into war, neutrals have, to an increasing degree, shown an inclination voluntarily to abandon the exercise of these rights. During World War I, many European neutrals prohibited the trade of their nationals with belligerents in many commodities, and by the Act of 1939, the United States prohibited American ships from trading with belligerents or traveling through proclaimed zones in the theater of hostilities. This act also required transfer of title to all goods shipped from the United States to belligerents in whatever vessels they went. Other neutrals have made similar self-denying ordinances.

(8) Neutrals have in the past insisted that hostilities must not occur in their territorial waters. They have even objected to hovering by belligerent war vessels outside of these waters. Going far beyond this, the American countries in the Declaration of Panama, in October 1939, warned belligerents not to engage in hostile acts in a zone 300 miles or more around the American continents except Canada. This warning was not observed by belligerents, particularly in the *Graf Spee* incident, and the American countries considered possible procedures for making it effective before the Japanese attack at Pearl Harbor involved them in the war. The difficulty of assuming responsibility for actually preventing hostilities in so vast an area has been recognized.

These changes have in practice tended to blur

the distinction between civilians and combatants, and to limit the rights of neutrals, thus extending the range of military action. But even more significant has been the blurring of the distinctions between war and peace, and between belligerents and neutrals. From the ending of the Napoleonic Wars to the beginning of World War I, wars were limited in time, area, and methods. They began and ended at determinable times and included definite belligerents. The Hague Conference of 1907 required that war be begun only by a declaration or an ultimatum with a time limit. There were, it is true, numerous interventions, insurrections, and pacifications, not rising to the dignity of war, but sometimes involving considerable casualties. They were, however, usually conducted by great powers against small or backward peoples, and did not cause serious international disturbance. They were considered police operations in contrast to war, which was regarded as a duel in which the belligerents were equal and must be treated impartially by neutrals.

The extraordinary rise of internationalism, and the extraordinary destructiveness of totalitarian war has, however, shaken the moral, economic, and political foundations of this concept of war as a legitimate and institutionalized procedure. The League of Nations Covenant went far toward abolishing war in the legal sense. "Resort to war" in violation of the Covenant was declared illegal and rendered the aggressor liable to economic sanctions by all members of the League. These members were at the same time bound to assist the victim of aggression (Article 16). Thus the essential feature of war in the legal sense, jural equality of the belligerents and jural impartiality of the neutrals, was eliminated in case war was begun in breach of the Covenant. While the Covenant left gaps through which legitimate war might creep, these were blocked by the Pact of Paris, signed in 1928 and subsequently ratified by nearly all the states of the world. Parties to this instrument "condemn recourse to war for the solution of international controversies, and renounce it as an instrument of national policy in their relations with one another." Furthermore, they "agree that the settlement or solution of all disputes or conflicts of whatever nature or of whatever origin they may be, which may arise among them, shall never be sought except by pacific means." Going even further, the members of the United Nations agree "to settle their international disputes by peaceful means" and to "refrain in their international relations from the threat or use of force against the territorial integrity or political independence of any state, or in any other manner inconsistent with the purposes of the United Nations."

The parties to these instruments proceeded to develop procedures for determining the aggressor and for imposing sanctions. A state engaged in hostilities, which refused to accept an armistice or other conservatory measures proposed by the consulting states, was provisionally considered an aggressor. A definition of aggression to determine ultimate responsibility emerged from the judgment of the Nürnberg Tribunal and proposals of the United Nations International Law Commission: it meant the threat or use of armed force across an internationally recognized frontier, for which a government, *de facto* or *de jure*, is responsible, because of act or negligence, unless justified by a necessity for individual or collective self-defense, by the authority

of the United Nations to restore international peace and security, or by the consent of the state within whose territory armed force is being used. (Q. Wright, "The Prevention of Aggression," *American Journal of International Law*, July 1956.) Sanctions included moral denunciation, application of the "Stimson doctrine" that the aggressor should not acquire any legal titles by his illegal action, economic embargoes, and the use of armed force.

While the application of these new principles was not always successful in preventing war or in thwarting aggression, the opinion continued that the international duel is incompatible with modern civilization, and that it may be both immoral and impolitic to treat the aggressor and his victim alike.

Aggressively inclined states have reacted to the same opinion by manifesting a disinclination to acknowledge that they are engaged in war. They have sought to represent their military activities as policing expeditions like the interventions and pacifications of the earlier period. In the hostilities from 1920 to 1956 there were no declarations of war except in the Chaco affair (1932-1935), in the wars against Germany and Japan in 1939, and in the pronouncement by certain Arab states in 1949 that they were in a state of war with Israel. The United States proclaimed neutrality only in the Ethiopian hostilities of 1935, and on the outbreak of World War II. The hostilities in Spain (1936), in China (1937), in Finland (1939), in Korea (1950), and in Egypt and Hungary (1956), though the first two each involved more loss of life than did the American Civil War, were not recognized as war in the legal sense.

Nonbelligerents, even if they have not applied sanctions, have considered themselves free to do so. The League recommended discriminatory action, not only in the Ethiopian hostilities but also in the Chaco, Far Eastern, and Finnish hostilities. The United States government, through the Export-Import Bank, made loans to China and to Finland, gave destroyers to Britain, and aided the Allies by lend-lease, all of which would have been incompatible with the international law of neutrality. The United Nations organized a police force to stop hostilities in Korea (1950) and Egypt (1956) and recommended cease-fires or armistices which stopped hostilities in Indonesia (1947), Kashmir (1949), and Palestine (1949). Similar methods to end hostilities in Greece (1947) and Viet Nam (1954) were undertaken by international action largely outside the United Nations.

Thus war, instead of being a status, which arises from the decision of the state which declares it or which begins hostilities with warlike intent and thrusts the status of belligerency or neutrality upon other states whether they wish it or not, has become a status which exists only insofar as the states of the world recognize it. If they choose to recognize the hostilities, not as war but as aggression, and to discriminate in favor of the victim, they are free to do so under the Covenant, the Pact, and other antiwar treaties. They are obliged to do so under the United Nations Charter if aggression is properly determined.

The consequence, therefore, of the intensification both of war *de facto* and of efforts to prevent such war, has been a tendency for war *de jure* to disappear. The Summit Conference

among the political chiefs of France, United Kingdom, the Soviet Union, and the United States in 1955 resulted in the common recognition that war with hydrogen weapons would be suicidal and that no state would voluntarily initiate it. The fear that such war might emerge through misunderstanding or the aggravation of a "small war" was, however, by no means eliminated. The distinction between states of war and of peace, between war and hostilities short of war, between belligerency and neutrality, have all become less precise, as have the rules defining belligerent and neutral rights.

Changes in the Law of Peace.—The decade of juristic optimism and of organized internationalism following World War I was characterized by a distinct lack of interest among jurists in the laws of war and neutrality and an extraordinary increase of juristic interest in the development of the international law of peace, especially the law defining procedures of international adjudication, legislation, and administration, and the law regulating international cooperation in matters of communication and transit, administration of mandated territories, protection of minorities, trade in opium and narcotic drugs, slavery and the slave trade, conservation of the resources of the sea, and others. The Permanent Court of International Justice, the International Labor Organization, and the League of Nations operated efficiently and, until the outbreak of World War II with increasing prestige in the nonpolitical fields.

Throughout this period, however, it was realized that these achievements were endangered by the continued insistence of states upon the free exercise of their military, political, and economic sovereignty. Efforts were accordingly made by international conferences to bring about military and economic disarmament and to require the submission of all international disputes to some form of pacific settlement. These efforts, while achieving some successes in the Washington Disarmament Treaties of 1922 and the considerable ratification of the optional clause of the Permanent Court of International Justice and the General Act of Pacific Settlement, were not adequate. Movements for economic self-sufficiency following the failure of the economic conference of 1927 contributed to the great depression of 1929, and to the rise of international tensions. Hostilities were renewed in 1931 with the Japanese invasion of Manchuria, and they rapidly spread, through Italian, German, Soviet, and further Japanese aggressions, to Ethiopia, Spain, China, Albania, Czechoslovakia, Poland, France, Britain, the Dominions, the Baltic States, Finland, the United States and most of the states of the world, carrying in their wake a reduction of international confidence, a weakening of the League of Nations and the Pact of Paris, a diverting of the energy of all states to military preparedness or to war itself.

The deteriorating situation led to new efforts to regulate war, taking form in new Geneva Conventions of 1929 and 1949 and in the London Conferences of 1930 and 1936, aimed at protecting civilians and the sick and wounded in war, and also to a new effort to prevent war through the United Nations, established by the San Francisco Conference near the end of World War II.

Many have become convinced that modern conditions of interdependence and rapid tech-

nological change require international legislative procedures to adapt state power to the needs of the community of nations, parallel with executive procedures to prevent violations of the law. The difficulties of these problems, however, cannot be minimized. Normal reliance upon coercing states as such was rejected by the makers of the United States Constitution and did not work under the League of Nations Covenant. Although a more organized plan for coercing states was contemplated by the United Nations Charter, it could not often be applied in practice because of the great power veto. Powerful states resent coercion and their nationally minded populations cleave closer to the aggressor government when external sanctions are imposed against it. Furthermore, the states applying sanctions suffer inconveniences and dangers and are apt to be hampered by a public opinion opposed to visiting hardships upon that section of the aggressor state's population innocent of wrongdoing.

No less difficult has been the problem of peaceful change. Even federations have not often transferred territory from one member state to another. Article XIX of the League of Nations Covenant which envisaged changes of territory and of inapplicable treaties, as an offset to the guarantee of the territorial status quo by Article X, was not successfully applied. President Woodrow Wilson's draft article from which these two clauses of the Covenant developed contemplated a closer relationship between them. In his thought, the territorial guarantee was to be subject to an international right of eminent domain, exercised by the League of Nations, and involving compensation to the state deprived of rights. He suggested: "The contracting powers unite in guaranteeing to each other political independence and territorial integrity; but it is understood between them that such territorial readjustments, if any, as may in the future become necessary by reasons of changes in present racial conditions and aspirations or present social and political relationships, pursuant to the principle of self-determination and also such territorial readjustments, as may in the judgment of three fourths of the delegates (at the assembly) be demanded by the welfare and manifest interest of the peoples concerned, may be effected, if agreeable to those peoples; and that territorial changes may in equity involve material compensation. The contracting powers accept without reservation the principle that the peace of the world is superior in importance to every question of political, jurisdictional boundaries."

Such a procedure might be useful, but it seems probable that a legislative authority which will gradually reduce the military and economic importance of boundaries may prove more practicable than such an authority to change the boundaries themselves. With freedom of interstate commerce and with the prohibition of interstate war, it has not been necessary to change boundaries of the states in the United States. Experience under the Articles of Confederation, as in the modern family of nations, suggests that forces of interdependence cannot function if sovereignty can erect tariff walls and prepare for military aggression without limitation. International law must assure freedom of trade and communication and security from military invasion across all frontiers as well as a moderate protection of the civil rights of individuals, especially the

freedom of opinion and the press. Only with the latter can the world be protected from the intense nationalism which may be produced by the propaganda devices now available when counter-propagandas are barred.

Human Rights.—The new institutions established after World War I and strengthened after World War II sought to effect changes to meet these requirements, but they have not achieved either justice or order in the world. There is a growing opinion that the task cannot be fulfilled unless international law recognizes that the state is for man, not man for the state, and establishes, in larger measure, common standards for the protection of human rights. It seems clear, however, in view of the persistent sentiment of nationalism, that such progress depends upon increasing identification in both public opinion and government policies of the national interest of each state with the universal interest of mankind.

Certain steps in this direction were taken before World War II, as for instance the right of petition accorded to the minorities and to the inhabitants of mandated territories, and the increasing tendency of jurists to treat individuals as subjects of international law, a tendency which gained some support from the practice of arbitral tribunals in adjudicating claims of aliens against the state of residence. Though formally such claims have been presented by the state of which the injured individual is a national, in fact the individual has often been recognized by the tribunal as the real party at interest.

These tendencies have received greater impetus in the "Declaration by United Nations" on American entry into World War II, and the United Nations Charter of 1945. These declarations called for the freedom and welfare of the individual rather than the rights of states. Organizations in the fields of relief and rehabilitation; food and agriculture; aviation and telecommunication; trade and finance; science, education, and culture; and technical assistance and atomic energy were established under United Nations auspices to serve human needs directly, as did the International Labor Organization which continued from the earlier period. The United Nations Charter, while founded on the principles of "the sovereign equality of members" and the obligation of members to settle disputes peacefully, to refrain from the threat or use of force in their relations, and to assist the United Nations in preventing aggression (Article 2), was declared to be the work of "we the peoples of the United Nations." Furthermore, among its primary tasks is the promotion of "universal respect for, and observance of, human rights and fundamental freedom of all without distinction as to race, sex, language or religion."

A practical exemplification of the direct relationship of the individual to the world community was exhibited in the Charter for the Trial of Major War Criminals concluded among the United Nations in August 1945. This charter defined crimes against the peace, war crimes, and crimes against humanity for which there should be individual responsibility, irrespective of the official position or governmental authorization of the defendant. The International Military Tribunal, established at Nürnberg in accordance with this charter, tried 21 Nazi officials indicted for one or more of these offenses, and a similar tribunal in Tokyo tried the principal Japanese

officials responsible for the war in the Far East.

The development of nuclear energy led immediately to proposals for monopoly control by an international agency of the natural resources and manufacturing facilities for making atomic weapons (Baruch Plan) and, while this proposal has not been accepted, a United Nations Atomic Energy Agency was established among 82 states in 1956 to assure cooperation in expanding the peaceful uses of atomic power (Eisenhower Plan).

THE FUTURE

International law will doubtless continue to balance the principle of national sovereignty against the principle of world society; but the rapid strides of science and technology in eliminating distances, augmenting powers of destructive aggression, and reducing powers of defense have created a demand to shift the center of equilibrium in the direction of world society. This has led to the institutions and legal principles accepted in the United Nations Charter. The sentiment of nationality and the tradition of sovereignty remain, however, as active forces. The governments, particularly of great states, hesitate to relinquish their prerogatives. Consequently the problem of establishing an international law able to maintain the world in dynamic stability will not be easily solved.

The difficulty was accentuated after World War II by the cold war. Opposition between two halves of the world, headed respectively by the Soviet Union and the United States, led to an arms race, political instability, and the incapacity of the United Nations to function as planned. The Soviet Union opposed the evolution of the United Nations as a curb on national sovereignty, hampered the work of that organization by frequent use of the veto in the Security Council, reduced its neighbors to a satellite status in an aggressive bloc to expand its system, and curtailed trade and communication across the Iron Curtain which separated that bloc from the rest of the world. The Western powers, while seeking to build the United Nations and its specialized agencies into instruments for rehabilitating war-shattered economies, for promoting human warfare, and for developing a sense of world solidarity, resisted any encroachment upon their "domestic jurisdiction" to deal with colonial, racial, and federal problems, organized blocs to oppose the Soviet system, and often dealt with security problems independently. The United Nations has, therefore, accomplished less than anticipated in the field of international security. It has not been able to achieve either atomic or conventional disarmament, to establish a permanent international force or to settle disputes directly involved in the "cold war." It has declared a universal bill of human rights and opened a convention on genocide for ratification; has recognized that action to suppress colonial revolts or minorities in such a way as to threaten international peace and security is subject to discussion in the General Assembly; and has brought about important political changes such as the partition of Palestine, the recognition of Indonesia and Libya, and the establishment of trusteeships in Somaliland and the mandated territories except Southwest Africa. It has also established an International Law Commission instructed to develop and codify the law concerning the rights and duties of states, international crimes, and the regime of the high

seas. States, however, became convinced that so long as the United Nations lacks capacity to make decisions because of the veto and lacks material forces to implement them, they cannot rely on it for security. Consequently, they have utilized the freedom given them by Articles 51 and 52 of the Charter to create regional and collective self-defense arrangements in such a way as to increase the insecurity they hoped to reduce.

It seems to be clear that international law cannot, without important changes, maintain order in a world divided by rival ideologies, and in which both nationalism and internationalism have reached the intensity and organization which they have in the 20th century. Ideological crusading must be subordinated to the stabilization of a society of coexisting nations and sovereignty of the state must be limited by appropriate laws and institutions in the military, political, and economic fields, in order that all peoples may advance in freedom and welfare through international cooperation for the common interest. The alternative appears to be a further isolation of national cultures and economies and a general diminution of human freedom and standards of living. The anarchy which results from extreme claims of sovereignty and ideological intolerance, and the wars which result from this anarchy, are incompatible with the progress of civilization in a rapidly shrinking world.

The future is uncertain, but the important development of the science and practice of international law, and the increasing number of individuals, organizations, and journals devoted to the subject since the establishment of the League of Nations, the United Nations, and the World Court suggest that international law will not disappear. The grave problems of sanctions and of legislation, of collective security and of peaceful change have not been solved, but the need to solve them has become greater than ever.

It remains to be seen whether, from the power rivalries of states, of regional arrangements, and of general international organizations, a more stable condition of affairs will develop in the shrinking world within which a new international law, forbidding aggression, demanding pacific settlement, protecting human rights, and facilitating cooperation for human welfare, can be maintained by suitable institutions. The activities of the United Nations in the autumn of 1956 were immediately successful in stopping the hostilities of Israel, France, and Great Britain in Egypt, and in mobilizing world opinion against the Soviet invasion of Hungary. While peaceful settlement of the problems of Suez, Israel, and the Soviet satellites proved more difficult, principles of international law were, under the initiative of the secretary general of the United Nations, accepted as guides for such settlements. This experience suggests that the distribution of power in the world may undergo changes toward a more stable equilibrium and a more effective United Nations, permitting a larger influence to international law.

INTERNATIONAL PEACE GARDEN. a memorial garden and park which straddles the international boundary between the State of North Dakota and the Province of Manitoba, Canada, in the Turtle Mountains area, about 15 miles

N.D. State Soil Conservation Committee

Aerial view of International Peace Garden.

south of Boissevain, Manitoba, and 12 miles north of Dunseith, N.Dak. It commemorates the long history of peaceful relations between the United States and Canada. Proposed in 1929, the memorial was made possible by gifts of land totaling over 2,300 acres by Manitoba and North Dakota. At its dedication in 1932, a stone cairn was unveiled bearing an inscription pledging the two nations to peace "as long as men shall live." Tourist and camping facilities were added in the 1930's, and after World War II the state and province cooperated in developing a mile-long

series of terraces and formal gardens along the international border.

INTERNATIONAL RELATIONS.
Private International Activities.—International relations in the broadest sense embrace all intercourse between persons belonging to different nations. Merchants and navigators; bankers; industrialists; tourists; churches, artistic, scientific, professional and athletic associations; trade unions, and chambers of commerce all engage in activities that cross national boundaries. The earliest records of civilization show some of these activities, already in progress. They have their origin in the fact that civilized man has never been able to satisfy his needs and desires within the limits of the political groupings that we now call nations or states. Their importance to the strength and welfare of the nation, particularly when they have to do with commerce, was early understood, and some effort was made to protect them from the interruptions incidental to the frequent quarrels of princes. Such, for example, was the purpose of the provision in the Magna Carta offering merchants from countries at war with England safety of person and goods on condition that English merchants were given the same treatment in the enemy country. The earliest compilations of international usage (which were quite unofficial) set out the rights and duties of navigators and merchants. Consular services for the protection of these adventurers in foreign parts, at first arranged by their own associations, were taken over by some states even before permanent embassies for the conduct of official relations came into use in the 15th century.

Public International Activities.—In countries where private enterprise is still favored, the vast international exchange conducted by individuals or nongovernmental organizations is distinguished from official or public international relations, in which the persons engaged act not in their private capacity but as representatives of their respective states. A large part of these public relations is concerned with the protection and advancement of the foreign interest of specific citizens and corporations, for the nation's ability to defend and maintain itself depends in large measure on the prosperous activity of its members. There is therefore no less general national interest in facilitating such activity than in keeping up the armaments and alliances which are the immediate instruments of national security. Under totalitarian socialist regimes, where the government takes direct control of all international relations, the distinction between public and private tends to disappear, as it also does in internal affairs.

Diplomacy and Human Relations.—Official foreign relations, apart from those of war, were once almost exclusively the business of princes themselves or their foreign offices. This was diplomacy, mysteriously carried on through the imposing embassies and legations maintained in foreign capitals and very remote in appearance from the ordinary concerns of the average man. It was through this machinery that governments kept themselves informed of favorable or threatening developments abroad, kept up the necessary

network of treaties on commerce, boundaries, mutual defense, arbitration, extradition and a mass of other international business, and smoothed out, or failed to smooth out, the conflicts of interest that constantly arose in the international competition for territory, resources, and friends.

Personification of the State.—The increasing scope and tempo of international intercourse and the general expansion of state business gave many other departments of government a hand in the formulation and conduct of foreign policy, while a growing realization of its intimate bearing on the everyday life of the individual gave rise to a demand for citizen participation in its direction. This expansion of scope, interest, and participation, together with the fact that the nation's power, prestige and security, and the issue of peace or war are so directly involved, accounts for the unique hold of these official relations upon public attention. International relations come to be thought of almost solely as the relations of France, Britain, the United States, Russia, and the 90 other "sovereign states" of the world. These abstractions are pictured as distinct beings in their own right, feeling, wishing, and acting in their own peculiar ways. We personify the state, and this mental trick obscures the fact that all international relations are human relations, complicated though they may be by the division of humanity into national compartments, and that the actors on the international stage are always human beings.

Uniformity and Change in Foreign Policy.—One consequence of this personification is a tendency to attribute an excessive fixity to the attitudes of governments in international affairs. It is true that geographical situation, material resources, cultural tradition, and historical growth make a sort of framework that limits the variations of response to external challenge and fosters a vein of continuity in foreign policy. To that extent there are French, British, American, and other national foreign policies that remain uniform in their broad lines over considerable periods. But the framework itself is subject to change by human action, and its significance may be radically altered by technological developments. Thus a succession of governments content to make the best of existing conditions may be followed by one determined to alter them by conquest or colonization; or again the invention of new modes of transportation or new weapons may change a policy of isolation to one of active participation in world politics. Growth of population may set up a demand for increased resources, and the response of government may be a new economic policy or a plan of territorial expansion. Ideas of what the nation needs, in other words notions of national interest, though to some extent hereditary, vary in response to a multitude of changing factors, and the objects and methods of governments vary with them. Prominent among these variables are the differences of individual character. Not even the most constant physical factors of environment operate automatically and directly upon policy; all exert their influence only through the refracting medium of human minds.

Students of international relations, or world politics, are always seeking constants among the shifting notions of national interest and the changing objects of policy. Some think they have found the universal determinant in the competition

for power. It is, they say, a uniform goal of the participants in world politics to maintain and if possible expand national power. Part of their proof lies in the historical and continuing value attached to what is described with some inexactitude as the balance of power.

Balance of Power.—It is true that governments have traditionally resisted and still resist the accumulation by a potential enemy of such a superiority or overbalance of power, either by armaments or by alliances, as would make national defeat likely in the event of war. It is also true that they try to prevent or to outmatch hostile accumulations of voting power in international organizations. What they really seek is not so much a general equilibrium as an overbalance of power on their side. The occasions on which governments have voluntarily surrendered power in order to achieve an equilibrium have been rare and dubious, while history is full of their unmistakable attempts to achieve a predominance. But, though balance in the sense of equilibrium is a misleading term in this context, the struggle to avoid losses and make gains of power accounts for much of the maneuvering associated with diplomacy. It is the essence of the "cold war," which is of course an ancient type of tension given new dimensions and a new name. In such struggles neither side seeks a mere equality or equilibrium: the aim of both is to gain and hold a lead in every element of power. With two gigantic concentrations of power, and only scattered and relatively weak groups of neutral nations uncommitted to either, the international scene is dominated by the explosive rivalries of the major blocs and their efforts to win the neutral groups or at least to prevent them from joining the opposing camp.

Power, Welfare, and Foreign Policy.—The power struggle is, then, a prominent feature of international relations. Nor is it eliminated by international organization where, however, in the measure of the organization's success, it does take on an importantly different, nonviolent form. But it is only by an excessive stretching of words that it can serve as the essential explanation of the general foreign policy of certain states or the occasional policy of others. Swiss governments, for example, can hardly be said to calculate national interest in terms of power. Even in the lives of stronger nations governments have sometimes been persuaded that changes in policy involving a voluntary shrinkage of international stature were imperative. Interests other than power, that is to say, have been given priority. Political leaders making the national power position their prime concern could hardly have countenanced the turn in 19th century Sweden from a large and adventurous military program to external peace and internal political-social reform and economic development or, later, have cooperated in the dissolution of the union with Norway. Nor does the power motive go far to account for the evolution of the British Empire into a Commonwealth of Nations whose members are free to secede at will. Finally, though there has been no little hypocrisy in official statements of devotion to the League of Nations or United Nations, the struggle for national power is an inadequate explanation of the residue of serious effort that has gone into international political organization. Addicts of the power thesis oversimplify and distort the

complex of factors and motives that influence responsible statesmen.

National Interests and International Relations.—Theoretically, governments in their foreign relations serve primarily the collective interests of the nation, championing the private activities of their fellow countrymen abroad only insofar as these redound to the general national advantage. Foreign policy, to the extent that it is a product of deliberate choice, may be defined as the plan by which governments seek to realize national aims in the international sphere. But because the plan is devised and executed by human beings, the calculation that precedes the choice of ends and means is only more or less detached from motives of private advantage. As objectives of policy the collective interests of the nation are at best only what the policy makers of the moment think they are, and statesmen are not proof against our human habit of assuming that what is good for us and our friends is also good for the nation. Powerful individuals and groups are therefore able from time to time to sway foreign policy in the direction of particular interests only nominally identified with the general good. The "devil" theories of world politics that find the real direction of international relations in the munition makers or captains of finance, melodramatically exaggerated as they have been, have some basis in reality. But, for the same reasons, foreign policy may be swayed by powerful individuals or groups seeking such broad human ends as universal peace and the worldwide advancement of living standards, and seeing the highest national interest in serving these ends.

Reason of State.—The state, being personified, was also deified. "Reason of State" became a commandment. This doctrine has served to excuse and even to glorify things done in the name of the state which on any other account would be condemned as immoral or even inhuman. It continues to be a dominating influence in international relations. Based upon the principle that self-preservation is the first duty of the nation and that the nation's constituted authorities alone decide when its existence is at stake and what means are appropriate to its salvation, the doctrine, though verbally repudiated by the statesmen of most countries, was implicit in the generally accepted view that nations had a right to go to war at their own discretion. It survives in the common opinion that the state has its own necessities that take priority over considerations of law or morality.

War.—Private war became illegal and obsolete as the local potentates of feudalism were compelled to submit to the central authority of the modern state. When that change was complete, the only war permitted was that authorized by a sovereign government. The state, in pursuit of its international aims, was thought entitled to the recourse to general violence that had now been forbidden to its subjects. Churchmen and lawyers tried to establish the principle that war without just cause was illegal, and much of what is now known as international law grew out of their endeavor; but princes insisted upon their own ideas of justice.

Contemporary international political organization is built upon treaties that purport to "outlaw," or to place far-reaching legal restrictions upon, war by states. The object is to substitute peaceful settlement of disputes for the age-old

free recourse to arms, and to guarantee national security by collective police action against aggressors. This effort is one of the distinguishing features of international relations in our time. The slowness with which it proceeds is due to the fact that its success presupposes a drastic change in habits of thought and feeling ingrained in men for centuries.

The groupings of human beings out of which the modern state grew were instruments in the competitive struggle for existence. Men found in them some protection against the marauding outsider and a means of success in their own marauding. The more or less constant state of war bred an enduring distrust and fear of foreign groups and a corresponding devotion to one's own. The state came to be regarded as something much more than a mechanism for human service. It assumed the character of end in itself—an organism whose needs were the supreme law. That is why great differences of moral and legal quality still distinguish the relations of state to state from those of man to man, and why it proves so difficult to subordinate the state to any higher authority.

A Law of Nations.—Yet from the earliest recorded times there has always been some effort to regulate the relations of state to state. Forms resembling those used in the legal relations of individuals within the state very early made their appearance in the arrangements that had to be made from time to time between rulers. We have records of treaties going back as far as the fourth millennium B.C. These were in the nature of contracts by which kings promised each other peace, settled boundaries, made alliances. Like many private contracts, they were accompanied by an exchange of oaths or of more material security to guarantee performance. Slowly, too, some unwritten understandings won general approval. Envoys sent by princes to do business with foreign rulers should have safe conduct on their missions. Wars should not be launched without a previous statement of grievances which the offending state might choose to remedy rather than take the risks of battle.

These rudiments of a law of nations, developing through Greek and Roman times, persisted through the Middle Ages. They were fostered by the church, the ecclesiastical influence on the whole favoring fidelity to promises and moderation in the use of force. Some corresponding development had long been in progress in the Near, Middle, and Far East; though such restraints, frail and sporadic enough between peoples of the same civilization, were even weaker in the relatively rare contacts between different civilizations.

With the Renaissance came a strong upsurge of ideas about a universal human law governing princes and peoples in their dealings with one another. Besides treatises on the law of nations coming off the new printing presses, ambitious plans of European or universal organization to prevent war and compel the peaceful settlement of disputes were circulated by jurists, poets, philosophers, and even kings. These blueprints were read, admired, and left on library shelves. But the body of treaty rules and customary forms continued to grow and, despite the absence of those agencies of enforcement that are found indispensable to national legal orders, it provided a routine in which much of the ordinary business of states could be transacted with peaceful effi-

ciency. It would be a long time yet before war ceased to be looked upon as a normal way of getting what any strong nation wanted badly; but the growing official habit of thinking about the relations of states in legal terms, coupled with the evolution of rational patterns of practice, eliminated some of the frictions out of which armed conflict is apt to spring.

The Conference System and the Concert of Europe.—Gradually taking practical shape in Europe was the notion of a certain collective authority and responsibility resting upon the greater powers to establish and from time to time repair or adjust a general framework of order sufficient at least to prevent the dissolution of the common culture in chaotic violence. The Congress of Westphalia, which in 1648 ended seven years of difficult negotiation with a general settlement of the religious, territorial, and political conflicts of the Thirty Years' War, was the first of a series of conferences that drew and redrew the political map of Europe. It was in the Treaties of Utrecht, 1712–1713, that the principle of distribution was described (Latin still serving as the written language of diplomacy) as *justum potentiae equilibrium*—a fair or just balance of power.

Characteristic of these distributions from Westphalia in 1648 to Vienna in 1815, and even later, was the fact that their fairness was decided exclusively by the great powers. Smaller states were carved up or auctioned off as make-weights in the bargaining of the great. But, even among the great, at least one speedily found the balance cramping on ambition and set about destroying it. After the ensuing struggle, another conference must adjust the distribution to a new constellation of forces. This highly opportunistic process of balancing and rebalancing came to be euphemistically known as “the public law of Europe.”

At the Congress of Vienna, where in 1815 the wreckage of the Napoleonic War was temporarily patched up, a new tendency made its appearance. The conferences began to make incidental additions of a humane or utilitarian character to this “public law.” The slave trade was to be checked by international cooperation. Navigation on rivers traversing more than one nation was to be open to the ships of all flags. At Aix-la-Chapelle in 1818 an agreed classification and precedence for the heads of diplomatic missions was established. The Concert of Europe though much more of an idea than an organization, expressed something of that sense of community which is the beginning of all law. At Paris in 1856 privateering was abolished, rules laid down regarding contraband and blockade, and a resolution adopted in favor of general arbitration. At the same time the Concert first extended formal recognition to a non-Christian country, Turkey.

From that time on the conference system rapidly expanded in subject matter and became worldwide in participation. Soon it was setting up the Universal Telegraph and Postal unions, the first in the long line of international service agencies. At Geneva in 1864 a convention was concluded for the care of the wounded. Four years later 17 governments joined in the Declaration of St. Petersburg prohibiting explosive bullets. The Hague Peace Conferences of 1899 and 1907, originally intended as meetings of the powers to plan disarmament and arbitration, did

contrive an elaborate though entirely optional procedure for arbitration, but were, paradoxically, best known for their detailed "Regulations" for warfare by land and sea and their code of rules on the treatment of prisoners.

The plan for a third Peace Conference was abandoned in the accelerating movement toward World War I. That immense calamity lent a short-lived urgency to plans for the organization of peace, which were now taken up by the governments. The League of Nations, with its bevy of ancillary agencies, was the result.

International Agencies and the State.—The proliferation since the middle of the 19th century of international agencies serving interests recognized as common to many peoples is an acknowledgment that the state is less and less adequate as a device for meeting the needs of modern life. If the trend continues, it must reduce the importance attached to the state and its power. As the individual's dependence upon the state for services is transferred to other organizations, these must win some share of his allegiance. The creation of such unions as the European Coal and Steel Community is a move away from state sovereignty. Though we are still far from general world government, each new international agency may prove a step in that direction. Knowledge that this is so explains much of the nationalistic opposition to international organization.

A prominent characteristic of modern international relations is the conflict between the desire of governments to maintain the state in its position as the supreme object of human loyalty, on the one side, and, on the other, the necessity of securing services that can only be rendered by international agencies taking over some of the powers of states. The security of the national domain and the national way of life is commonly regarded as the prime function of the state. But the establishment of the League of Nations in 1919 was an official admission that the accumulation of national armaments is not a solution and that lasting security calls for permanent organization broader than the state. The League failed to win security for its members because neither governments nor their peoples were ready to transfer to it the formal authority and material power necessary.

The central debate in the United Nations is a phase of the same conflict, sharpened by the advent of weapons of mass destruction, between the traditional image of the state and the requirements of a collective security system. This debate is not one that divides East from West or the totalitarian from the democratic nations. It is common to humanity. As modern weapons make war, with its threat of total destruction, a less and less usable instrument of national policy, the search for other means of settling conflicts of interest takes on a desperate urgency. Hitherto, the search for public order has found its goal only in central authority exercising a monopoly of force. The international movement in that direction has brought great changes in the relations of states. As was shown in the Suez conflict of 1956, some restraining influence had been achieved even over the conduct of major powers. The scramble for colonies had been checked, the treatment of dependent peoples brought under supervision. It was no longer easy to manipulate small nations. Their independence had found a measure of protection in the United

Nations. But the limits of that protection were tragically demonstrated in Hungary while the Suez crisis was urgent. In that case one of the two greatest powers found it easy to defy all the restraints that contemporary world organization could bring to bear. International relations had not yet been transformed from the intermittently violent intercourse of states priding themselves on their sovereignty to the legally ordered relations of subgroups in a strongly organized universal society.

INTERNATIONAL SOCIETY OF CHRISTIAN ENDEAVOR, an international, interracial, and interdenominational movement, with societies for all age groups in Protestant evangelical churches. The society includes groups in the United States, Canada, and Mexico.

The first Christian Endeavor Society was organized Feb. 2, 1881, in the Williston Congregational Church, Portland, Me., by Dr. Francis Edward Clark (q.v.). Since then the movement spread until in 1957 the World's Christian Endeavor Union included approximately 3,000,000 members in 80 denominations in over 50 countries or island groups.

Christian Endeavor has a fourfold purpose: (1) to lead young people to commit themselves to Jesus Christ as Lord; (2) to bring them into the life of the church; (3) to sustain and train them for active Christian service; and (4) to release them through all channels of human activity in the service of God and man. The Christian Endeavor pledge is the basis for membership.

Societies are organized into local, county, district, state or provincial, and national unions. The headquarters for the International Society and the World's Union is in Columbus, Ohio. The official publication is *The Christian Endeavor World*, issued monthly, and the society's motto is "For Christ and the Church."

INTERNATIONAL TELECOMMUNICATION UNION (ITU), an international body whose chief purpose is "to maintain and extend international cooperation for the improvement and rational use of telecommunication." Formed in 1932, at Madrid, it replaced the International Telegraph Union, established at Paris, 1865. Its structure consists of a plenipotentiary

conference, administrative conferences, and several permanent organs: an administrative council, a general secretariat, the International Frequency Registration Board (IFRB), the International Telegraph and Telephone Consultative Committee (CCITT) and the International Radio Consultative Committee (CCIR). The seat of the union in 1954 was Geneva, Switzerland.

INTERNATIONAL TELEPHONE AND TELEGRAPH CORPORATION (IT&T), an American corporation primarily engaged in the development and manufacture of electronic equipment either directly or through subsidiaries in the United States and abroad. Its 37 laboratory and manufacturing units comprise 80 principal plants in 20 countries: the United States, Argentina, Austria, Australia, Belgium, Brazil, Canada, Chile, Denmark, England, France, German Federal Republic, Italy, Norway, the Netherlands, Puerto Rico, Portugal, Spain, Sweden, and Switzerland. The corporation also has 12 telephone, radiotelephone, and radiotelegraph operating companies in seven countries: Argentina, Bolivia, Brazil, Chile, Cuba, Peru, and Puerto Rico; two marine radio companies in two countries: England and Spain; and a controlling interest in the American Cable & Radio Corporation, whose subsidiaries are All America Cables and Radio, Incorporated; The Commercial Cable Company; Mackay Radio and Telegraph Company; and Sociedad Anónima Radio Argentina. Altogether, IT&T employs about 125,000 persons.

Principal products of the IT&T system include wire and radio communication equipment of all types, radar and radio aids to navigation, electronic systems and equipment, and components. Its sales organization has outlets throughout the free world, where it is an important supplier to both governments and private industries. Important contributions of its research programs include microwave radio, automatic direction finders, selenium rectifiers, ILS (instrument low-approach system), TACAN (tactical air navigation), and a variety of systems and devices in the growing field of automation.

INTERNATIONAL TRADE ORGANIZATION. See **FREE TRADE.**

INTERNATIONAL TYPOGRAPHICAL UNION (ITU), a labor union of skilled printing trades craftsmen, the first of the craft unions in the American labor movement to be organized on a national scale. On May 5, 1852, journeymen printers from typographical unions in 14 cities, meeting in convention in Cincinnati, Ohio, organized the National Typographical Union, by which title it operated until 1869, when a new constitution was adopted, accepting affiliation of the Canadian printing trades unions and changing the name of the organization to the International Typographical Union.

The ITU has a membership of more than 100,000 men and women—all journeymen and apprentices employed in composing rooms and mailing rooms of newspapers, trade plants, book and job publishing houses, and commercial printing establishments. There are more than 800 subordinate typographical and mailer unions of the International Typographical Union located in cities on the North American continent and

Hawaii. The membership comprises printers, mailers, proofreaders, linotype operators, machinists, photocomposition experts, rulers, paste make-up artists, job or ad setters, stone hands, lineup men, typesetter operators, press operators, and dozens of other skilled craftsmen doing jobs indigenous to the printing and publishing industry.

As a pioneer among the labor unions of the nation, the ITU played a major role in bringing about the formation of the American Federation of Labor. Delegates representing other organized trades were called together by the ITU for a meeting in Pittsburgh on Nov. 15, 1881, which resulted in an organization known as the Federation of Organized Trades and Labor Unions of the United States and Canada. Following minor changes and realignments, this congress later became the American Federation of Labor. In 1935, Charles P. Howard, then president of the ITU, was one of the 10 men who formed the Committee for Industrial Organization (CIO).

Within the printing industry itself, the ITU also brought into being four other unions of allied craft workers. Before local unions of printing pressmen, bookbinders, stereotypers and electrotypers, and photoengravers established their own autonomous international unions, they were organized and chartered by the ITU. In 1896 local unions of both printing pressmen and bookbinders were released from the jurisdiction of the ITU and formed their own international unions. The stereotyper and electrotypewriter members took similar action in 1901, and were followed by the photoengravers in 1904. Since 1911, the five international printing trades unions have maintained an alliance through the International Allied Printing Trades Association, formed in that year for the purpose of joint ownership and control of the allied printing trades Union Label.

The ITU has been in the forefront of the labor movement in gaining for its members fair wages, a shorter workday, fair working conditions, protection of the rights of the individual under union laws, and contracts with employers. The first of the international unions with a pension system (begun in 1908) and a mortuary benefit plan (since 1891), the ITU has also maintained the Union Printers Home in Colorado Springs, Colo., for the care of its aged and incapacitated members since 1892.

P. A. M. MARTIN,
Union Label and Public Relations Department,
International Typographical Union.

INTERNATIONAL UNION OF GEODESY AND GEOPHYSICS (UGGI), an organization formed in 1919 as a constituent union of the International Research Council (now the International Council of Scientific Unions). It comprises the international associations of Geodesy, Seismology and Physics of the Earth's Interior, Geomagnetism and Aeronomy, Physical Oceanography, Vulcanology, and Scientific Hydrology. The objectives of the UGGI are threefold: (1) to foster studies relating to the size and shape of the earth; (2) to initiate, facilitate, and coordinate geodetic and geophysical research requiring international cooperation; and (3) to provide for discussion, comparison, and publication of results.

Membership in the UGGI is open to any nation sharing the maintenance expenses of the union.

Within a country, the group having formal ties with the UGGI usually is either the government itself or the national academy of sciences. In 1957, the UGGI had 46 members: Argentina, Australia, Austria, Belgium, Canada, Chile, Colombia, Czechoslovakia, Denmark, Egypt, Finland, France, German Federal Republic, Great Britain, Greece, Haiti, Hungary, India, Indochina, Indonesia, Ireland, Israel, Italy, Japan, Mexico, Morocco, Netherlands, New Zealand, Norway, Pakistan, Peru, Philippine Islands, Poland, Portugal, Spain, Sudan, Sweden, Switzerland, Syria, Thailand, Tunisia, Turkey, Union of South Africa, United States, Union of Soviet Socialist Republics, and Yugoslavia.

The main administrative and policy-making body of UGGI (especially in matters involving finance) is the Council, on which each member country has one representative. The Executive Committee is a smaller body whose primary function is to make decisions on urgent technical and administrative matters requiring action between General Assemblies. The final authority in all matters of the union (scientific, administrative, and financial) is the body of delegates from member countries meeting each three years in a General Assembly. General Assemblies have been held in Rome (1922), Madrid (1924), Prague (1927), Stockholm (1930), Lisbon (1933), Edinburgh (1936), Washington (1939), Oslo (1948), Brussels (1951), Rome (1954), and Toronto (1957).

INTERNMENT. See *ENEMY ALIEN PROBLEMS—Internment*.

INTERPELLATION, ĭn-têr-pê-lă'shŭn, in law, the act of demanding an official explanation of a member of the government, as in France and some other European countries. It is used more frequently in Italy and France than elsewhere. After due notice, any member of the particular legislative body may interpellate the ministry, and this often results in a general debate. Frequently a ministry resigns as a result of an interpellation. The right of permitting or refusing an interpellation rests with the legislative body, not with the ministry. An interpellation is followed usually by a vote of confidence or of want of confidence in the government.

INTERPRETATION, ĭn-têr-prê-tă'shŭn, in law, the art of determining the meaning of a speaker, or a writer, or of the parties to a written instrument, as a contract, deed, or the like. Courts of equity, in their interpretation and construction of instruments, follow the same rules as courts of law. The terms interpretation and construction, while frequently used interchangeably by some writers, should be differentiated according to others. In interpretation, they contend, the court decides simply the meaning of words and sentences, whereas in construction the court decides what is their legal effect. Interpretation is merely logical reasoning, while con-

struction is legal reasoning, these writers insist. The two terms, nevertheless, in practice at least, are generally used with identical meaning. The rules for interpretation vary to some extent with the particular class of instrument in dispute. For instance, wills are liberally construed, as the testator is not presumed to know the legal significance of all the terms he employs, but is held to use such in their popular meaning. On the other hand, a deed is generally construed strictly and against the maker when there is ambiguity. A contract must not be strictly nor liberally construed, but the intention must be drawn in the light of surrounding circumstances, as customs of the place or time, social conditions, and the like. Statutes abrogating the common law, as well as penal statutes, must be strictly construed. The same rule is applied to statutes affecting private rights. On the other hand, statutes designed to prevent fraud are liberally construed, and statutes must generally not be construed so as to operate retrospectively.

Some general rules of interpretation are as follows:

(1) The meaning of a word, clause, or other part of an instrument must be construed in the light of the whole instrument. Such disputed part may have its ordinary meaning entirely changed by this rule. (2) The meaning of the maker of an instrument is to be taken from what is therein contained and also from what may be fairly implied by custom or the like. (3) Due weight must be given to the construction placed upon the instrument by the parties themselves. (4) Words are to be taken in their ordinary meaning unless the writing or the attending circumstances indicate a contrary intention. (5) Where two interpretations are possible, that is to be preferred which is fair and reasonable. (6) Usually ambiguous language is to be construed against the maker of a private writing, as a contract or a deed.

In addition to the foregoing list, which is not complete, a large number of special rules have been framed to fit particular cases.

INTERPRETATION OF DREAMS (in German *Die Traumdeutung*), a book by Sigmund Freud (1900; translated by A. A. Brill, 1913) which has become a fundamental part of modern psychiatric therapy. It interprets the mind as an interfunctional unit of the Ego (the conscious, rational faculty), the Super-Ego (the Censor, or moral faculty), and the Id (the unconscious, irrational faculty). In presenting dozens of actual dream analyses, Freud demonstrates that dreams are neither meaningless nor prophetic, but are intelligible psychic productions. All dreams are symbolic fulfillments of wishes and desires suppressed by the Super-Ego. Freud notes three fundamental dream mechanisms: (1) Condensation, the fusing of various elements in the Id for economical transference to the Ego; (2) Displacement, the transferring of psychic importance and stress from the true objects in the Id to apparently trivial objects in the manifest dream; and (3) Dramatization, the embodiment of abstract ideas or emotions in visual terms. All of these processes also serve to disguise the expression of the suppressed wish from the Super-Ego. Since there is no standard, universal symbolism in dreams, the dream-analysis depends upon the dreamer's free-association of the manifest dream-content in terms of his own life experience. The forgetting of dreams is the belated activity of the aroused Super-Ego.

INTERSTITIAL COMPOUNDS. See *INTERMETALLIC COMPOUNDS*.

INTERVAL, in music, is the distance or difference of pitch, arithmetically expressed, between any two tones of a given scale. Occidental nations, including those of the Americas, employ the diatonic scale (see *SCALE*), an octave comprising five tones and seven semitones, named after the first seven letters of the alphabet. The affix of a flat or sharp before a note denotes its quality but does not affect its name, and the eighth note, being in unison, commences a new octave. Taking the scale in the key of C major the various intervals are: minor second = E-F or B-C; grave major second = C-D, F-G, A-B; grave minor third = D-F; minor third = E-G, A-C, B-D; major third = C-E, F-A or G-B; perfect fourth = C-F, D-G, E-A, G-C', or B-E'; acute fourth = A-D'; acute augmented fourth = B-F; grave diminished fifth = B-F'; grave fifth = D-A; perfect fifth = C-G, E-B, F-C', G-D', A-E; minor sixth = E-C', A-F', B-G'; major sixth = C-A, D-B, G-E'; acute major sixth = F-D'; grave minor seventh = D-C', G-F', B-A'; minor seventh = E-D', A-G; seventh = C-B, F-C'; octave = C-C', D-D', and so on. By taking various notes of the diatonic scale as starting points and measuring known intervals from these, we arrive at intermediate notes of the scale, of which the following are examples: C# minor third below E; D# minor second below E; Eb minor third above C; Ab minor sixth above C; Bb minor seventh above C; B# 3 major third above C. The difference of pitch between C and C# or between D and D# is called a semitone, and an interval increased or diminished by a semitone is said to be augmented or diminished. This applies especially to the interval of a fourth or a fifth, which with the octave are said to be perfect, because any augmentation or diminution mars their consonance. The major sixth or third may, however, be diminished to a "minor" sixth or third without destroying the consonance; and the term "minor" is also applied to the diminished second or seventh. Intervals confined within the octave are simple, when they exceed it compound; the octave beginning a new series, the ninth is the octave of the second, and so forth.

INTERVENTION refers in international law to the dictatorial interference by a state in the internal affairs of another state or in the relations between two other states. It is formally forbidden by a number of treaties, especially among American states, and has been described as illegal in essence and to be justified only by its success.

Intervention is distinguished from mediation, or the offering of advice by a state after a request by other states, and from representations or protests which concern the demanding state's own interests or rights. It is also sometimes distinguished from interposition, or forcible action by one state in the territory of another to protect its nationals, and from defensive action to prevent an immediately threatened aggression. It may take the form of either military or diplomatic action; but diplo-

matic intervention implies resort to force if the demands are not complied with.

The motive of intervention is political, rather than legal. The United States has, in pursuance of policies related to the Monroe Doctrine (q.v.), intervened in Caribbean republics—in Cuba to establish the independence of that state, and in others to maintain order and international obligations. It has been party to treaties which permitted intervention in Cuba, Santo Domingo, Haiti, and Panama, although these treaties were subsequently terminated in connection with the "good neighbor" policy.

Great powers have frequently intervened, sometimes collectively, to prevent a state from getting so powerful as to disturb the balance of power. A system of international relations based on an equilibrium of power can hardly avoid occasional interventions of this kind. Intervention to stop gross inhumanities against minorities or dependent peoples have also occurred, and have been considered justifiable if the purpose was genuinely humanitarian. Often such interventions have veiled political purposes.

The League of Nations Covenant declared that "the League shall take any action that may be deemed wise and effectual to safeguard the peace of nations," and the United Nations Charter gives the Security Council "primary responsibility for the maintenance of international peace and security." Action authorized in pursuance of these provisions has sometimes been called "collective intervention," and is undoubtedly legal if in pursuance of the authority given the organization by its members.

The problem of preventing circumstances from arising which will induce states to intervene in the affairs of others is the major problem of international law and international organization, and can hardly be solved without in some degree subjecting the sovereignty of states to the world order. Nations continue reluctant, however, to surrender their sovereignty in this manner.

QUINCY WRIGHT,
Professor of International Law, University of Chicago.

INTESTACY, the legal state of a person dying without having disposed of his property by last will and testament. In Britain, formerly, intestacy did not affect real estate, which was disposed of in accordance with the rule of descent. Legislation, which became effective there on Jan. 1, 1926, provided that both real and personal property shall devolve in the same way. The effect of intestacy in the United States varies in accordance with the laws of inheritance fixed by each of the states. Intestacy may be complete, as when a valid will is not left by the dead proprietor; or partial when the extant will only provides for the distribution of part of the property where a testator failed to make a residuary clause. In these cases the property passes to the heirs or next of kin of the decedent in accordance with the laws of the place where the property is.

The distribution under intestacy by the statutes of the various states of the United States may vary, but as an example in a common situa-

tion when a deceased is survived by husband or wife and children, one third of his estate is apportioned to the surviving husband or wife, and the remaining two thirds is divided equally among the children. Should there be a predeceased child with three grandchildren, such grandchildren would take the share of the predeceased child per stirpes, that is, a distribution by representation.

Actually, the law of the state makes the will of the decedent in cases of intestacy. The necessary steps for the administration of the property of an intestate is begun by filing a petition for letters of administration, obtaining jurisdiction of the necessary parties, and the issuance of the letters by the surrogate. There being no executor, the surrogate appoints an administrator, usually a person interested in the protection and conservation of the property. The surrogate may require the administrator to file a bond for the faithful performance of his duties. Usually those most closely related to the deceased are entitled to receive letters of administration in preference to one who is not so closely related. See DESCENT AND DISTRIBUTION; HEIR; INHERITANCE.

INTESTINE, BOWEL, or GUT. In man and the higher animals, that portion of the alimentary tube or canal lying between the stomach and the anus. The human bowel is divided into a small and a large intestine, the two parts varying in structure, movement, and function. The small intestine originates at the pyloric end of the stomach, and its first 8 to 10 inches form the duodenum. This section is divided into several [usually four] different portions and lies deeply within the upper abdominal cavity, embracing the head of the pancreas. Some 4 inches below the pylorus, is situated the opening of the common duct of the gall bladder and the pancreas through which bile and pancreatic juice are discharged into the intestine. At its end, the duodenum merges with the jejunum, the name applied to the upper two fifths of the small intestine, the lower three fifths being known as the ileum. Differences in gross structure of these two portions of the small intestine are not marked immediately, and only in its lower or terminal end does the ileum show distinct characteristics and definite changes. In general the jejunum is to be found in the left and upper portion of the peritoneal cavity, and has thicker walls than the thinner ileum, which occupies the lower portion of the belly cavity. The lumen of the small intestine, from the duodenum down, gradually becomes less, so that at the cecum its diameter is but little more than an inch as contrasted with nearly two and one half inches in the duodenum. The ileum is inserted at a point several inches above the lower limit of the cecum, which is the actual beginning of the large intestine. The cecum itself is a blind pouch lying in the lower right portion of the abdominal cavity, from which it continues upward as the ascending colon as far as the under surface of the liver. There it becomes the transverse colon. At its lower and posterior portion the cecum gives off a functionless organ well known to fame, the vermiform appendix (see APPENDICITIS). From its beginning near the liver and gall bladder, the transverse colon passes across the peritoneal cavity, within the folds of the great omentum and beneath the lower border

of the stomach, to the region of the spleen, where it turns downward at the splenic flexure, continuing its course as the descending colon. As it descends it becomes curved, somewhat like the letter S, forming the sigmoid flexure, the beginning of the rectum. The latter passes over the brim of the bony pelvis deep into the pelvic fossa, ending at its outlet, the anus (see COLON; RECTUM). The small intestine is usually about 23 feet in length, the large bowel being about 5 feet. In anatomical structure both portions of the alimentary canal have four coats, known from within out as the mucous, the submucous, the muscular, and the serous or peritoneal. The muscular layers contain both longitudinal and encircling fibers which by their contractions accomplish the movement known as peristalsis. In the small intestine, which is concerned largely with absorption of nutrient material, the result of digestive processes, the mucous membrane is thrown up into permanent folds or rugae, each extending more than halfway around the inside of the bowel, the result being that a large area is provided for absorptive processes. The inner surface is provided with minute, fingerlike projections called villi, each having a large absorbing vessel in the center. At the bases of the villi are tubular and branching glands [of Brunner and Lieberkuhn] that penetrate deep into the mucous membrane. Scattered irregularly over the surface are small collections of lymphoid tissue [the so-called solitary follicles]. In the ileum these follicles form collections known as Peyer's patches, and it is these which are attacked in typhoid fever, being the site of ulcers and occasional perforations. The muscular coat of the bowel already mentioned consists of two layers: an inner one, running about the circumference of the intestine; and an outer one, or longitudinal layer. The large bowel or colon has neither folds nor villi, its absorbing power being mainly for water. It is not as movable as the small intestine since it is fixed to the posterior wall of the peritoneal cavity except in the transverse portion, which has considerable mobility. The entire bowel is well supplied with a network of blood vessels contained within the mesentery or supporting peritoneal fold, by which it is attached to the posterior wall of the abdominal cavity. It has also a complicated nerve supply governing its secretory function and peristaltic action (see PHYSIOLOGY).

Diseases of the Intestine.—Intestinal diseases should be considered as including all disturbances referable to any part of the small or large bowel, from duodenum to anus. The general and all-inclusive term for these maladies, or at least most of them, is intestinal dysfunction. Interference with normal function of the intestine does not mean necessarily the existence of any structural change in the organs involved. Many manifestations, such as constipation, diarrhea, distention, abdominal pain, and so on, may be of reflex origin and may show no evidence of actual pathology. For this reason, intestinal indigestion, intestinal stasis, dyspepsia, and the like must be considered as vague terms which fail to describe a particular disease. Any classification of intestinal diseases of a medical or nonoperative nature will include constipation, diarrhea, intestinal neuroses, melenema, fatty stools (steatorrhea), food poisoning (ptomaines, botulism), ulcerative colitis, diverticulitis, and

perhaps regional ileitis, to mention some of the more important. Some of these medical conditions may become of surgical interest in certain cases.

The occurrence of intestinal parasites does not of itself constitute a disease but merely an infestation of the intestinal tract which may cause symptoms. Among surgical conditions affecting the intestine may be listed appendicitis, intestinal obstruction, tuberculosis, and malignant tumors. Regional ileitis is also of surgical importance. Gastric and duodenal ulcers [peptic ulcer], duodenitis, and hemorrhoids should be regarded as pertaining to pathologic conditions of the stomach and anus, respectively, rather than to the intestine itself (see *STOMACH*; *ANUS*; *HEMORRHOIDS*).

Constipation.—This is a functional disorder, and does not constitute a true disease, since it is caused by some disturbance of the regulatory mechanism of the bowel. It may be acute or chronic, and the portion of the bowel involved is usually the colon and especially the rectum, and not the small intestine. Among many conditions responsible, any or all of which may be present, may be mentioned insufficient fluid intake, improper diet, lack of exercise, careless and irregular bowel habits, and the abuse of laxatives (see *CONSTIPATION*).

Diarrhea.—This is the reverse of constipation, and is not a disease but a symptom. The acute variety may be the result of infection involving the intestinal tract, such as food poisoning, bacillary dysentery, amebic dysentery, ulceration of the colon, infestation by intestinal parasites which cause irritation, and the like. It may arise also from ingestion of irritative metals, such as arsenic, lead, and mercury. The cause of the chronic form is often obscure and difficult to determine and must be sought for among a host of diseases, including ulceration of the colon from tuberculosis, bacillary dysentery, pernicious anemia, leukemia, sprue, hyperthyroidism, and malignant disease of the colon although the last is usually associated with constipation. The underlying cause must be ascertained before effective treatment can be instituted.

Neurosis as Cause of Intestinal Disorder.—Neuroses, manifested by bowel dysfunction, are extremely common. They are often disposed of by such terms as indigestion, spastic colitis, mucous colitis, and irritable colon. Many persons afflicted with a neurosis, who are really not at all ill, become "bowel conscious," fretting over the mildest of symptoms and examining each stool with meticulous care and anxiety. Frequently such persons regard mucous, a constituent of normal colons, as indicating the presence of disease, and it is difficult to wean them from this belief. In spite of the chronicity of most neuroses and the complaints of those having bowel symptoms, the lack of interference with the general health of those affected, together with the fact that no blood, pus, or parasites are observed in the stools, furnish strong evidence against the presence of any actual disease.

Melenema.—This is a general term to indicate the passage of blood from the anus, and is not in itself a disease. The symptom may be discovered by accident, is often unaccompanied by pain, and is not noted in many cases since the individual may not see his bowel movement.

If the passage of blood be considerable it will cause a feeling of uneasiness and perhaps of faintness. In any event, the symptom is to be regarded with seriousness. Unless the loss of blood can be established by examination as coming from hemorrhoidal veins at the anus (piles), the cause should be searched for until it can be ascertained with certainty. The commonest sources of bleeding outside of hemorrhoids are anal fissure, rectal ulcer, and malignant tumor of the colon and rectum. Occasionally blood will issue from portal obstruction in the liver or from ruptured hemorrhoidal vessels high in the colon as a result of far advanced arteriosclerosis. Blood arising from the stomach, duodenum, and biliary passage is generally dark in appearance, due to partial decomposition in its passage through the digestive tract (so-called tarry stools).

Colitis.—Inflammation of the colon, of any degree of seriousness other than that arising from causes already mentioned, is generally chronic. In course of time the colon becomes congested and its mucous surface eroded. In advanced cases these eroded areas or ulcers show deep craters, and the diseased areas may coalesce to form a single large ulcer. Eventually the bowel becomes indurated and inelastic, with a considerably narrowed lumen. Symptoms may persist for years, with gradual decline in health and marked loss of weight. The disease is not particularly common, and is confined largely to elderly people. Another disease seen in this age group is diverticulosis [dilatation of the colon in certain areas] and its companion diverticulitis. The latter may become serious, and may necessitate surgical intervention if an abscess forms or if the area becomes the seat of malignant tumor.

Regional Ileitis.—This is a nonspecific, granulomatous, inflammatory disease involving the terminal ileum. Although it had been recognized many years before, the disease was first described adequately in 1932. At first thought to be rare, it is now regarded as fairly common. No single bacterial, virus, or chemical agency can be assigned as a cause. The disease resembles tuberculosis of the bowel and also certain forms of dysentery. While localized generally in a small section of the ileum, several feet of small bowel may become involved after several years, the process even extending to the jejunum. It is frequently complicated with other intestinal diseases and with intestinal fistula. It has been mistaken for acute appendicitis. The symptoms are abdominal pain, distention, failure of digestion, and loss of weight, together with recurring attacks resembling intestinal obstruction. After a considerable period of months or years the segment of intestine affected loses its elasticity and becomes cicatrized and inelastic, so that it is practically functionless. The diagnosis is suggested by the symptoms, and especially by the presence of an abdominal fistula which refuses to heal. It is confirmed by X-ray findings. The treatment is not always successful. Medical treatment is directed usually to diet, which must be such that the damaged bowel will absorb it with the least irritation possible, and to the administration of chemical foods by mouth or by injection into the circulation if nourishment cannot be borne by the usual channels. Surgical treatment may involve resection of the diseased intestine in part, or anastomosis of the intestine

so as to bypass the diseased segment, allowing the intestinal contents to pass through healthy intestine and leaving the diseased loop in situ.

Acute Appendicitis.—This is a bacterial infection often followed by suppuration (perforation) of the vermiform appendix (see APPENDICITIS).

Intestinal Obstruction.—This is an extremely acute intra-abdominal calamity of the utmost gravity. Its causes are manifold, including constriction of the bowel from pressure (such as bands of tissue which compress it), hernia (in which a loop of small intestine is held prisoner by the hernial ring so that it cannot escape into the abdominal cavity), intussusception (the telescoping of one loop of bowel into another; seen most often in infants), narrowing of the lumen of the bowel from any cause (as malignant disease or the action of caustics), impaction of feces, pressure of huge collections of gallstones, foreign bodies lodged in the intestines, and masses of intestinal worms. Still other causes, often most difficult of diagnosis, are thrombosis and embolism of a vessel supplying a segment of intestine and resulting in localized intestinal gangrene from failure of the blood supply. Any obstruction of the small bowel, whether from pressure, circulatory failure, or of mechanical or static origin, will result in an alarming train of symptoms. There is severe abdominal pain, vomiting (after several hours), which in late stages becomes fecal, abdominal distention without relief though bowel movements or the passage of gas, and mounting toxemia and prostration. If unrelieved by surgery within a short time of onset, the patient succumbs. The object of surgical intervention is to relieve the obstruction wherever it is found and to aid the paralyzed bowel to regain its tone and function. The toxic obstruction following operations (especially where peritonitis is present [ileus] in which the small intestine is paralyzed), is susceptible of relief through the use of lavage, using a special nasal rubber catheter running to the duodenum, maintained in place in connection with a negative pressure apparatus which keeps the stomach empty until the paralyzed bowel begins to function. Chronic intestinal obstruction involves usually the large intestine. If caused by foreign bodies or impacted feces, it is often relieved by simple measures. If the foreign body cannot be removed thus, or if a tumor be present, appropriate surgical intervention is indicated, according to the nature of the case.

Malignant Disease of the Intestine.—This is confined almost entirely to the colon and rectum. There are comparatively few tumors of the intestinal tract which are nonmalignant. Most new growths of the bowel are carcinomatous or adenocarcinomatous. A favorite site is the sigmoid colon, with the rectum next in order of frequency. Fortunately for the success of surgery, most tumors of the colon can be diagnosed and attacked before metastasis has occurred to other parts of the body. However, not all cancers transfer cells late instead of early, and operative interference should never be delayed unduly. The most favorable time is when the diagnosis is made and the surgeon indicates he is ready. The symptoms of intestinal cancer are often unnoticed or given only slight attention by the patient, since they are apt to be general. Thus gradually increasing and obstinate consti-

pation is the rule. There is gradual but steady loss of weight, increasing pallor and failure of strength, not to be accounted for by the everyday life of the patient. Anemia develops and then cachexia, the latter becoming so noticeable that acquaintances will remark it. Sometimes, but by no means always, a tumor can be felt through the abdominal wall. Occasionally, blood will be seen in the bowel movements. Diagnosis can be made usually by rectal or sigmoidoscopic examinations, supplemented by X-ray studies. The course of the disease is a few years at most unless resection of the diseased bowel can be done, with removal of the tumor and providing for end to end anastomosis; or if that is impossible and the anus must be removed with the diseased rectum, an artificial anus. If the operation can be completed before transference of malignant tumor cells to other locations has occurred, a complete cure is generally possible.

INTIMIDATION. See CORRUPT PRACTICES ACTS.

INTONING, the practice of delivering prayers in the recitative form. Intoning differs little from chanting: in the latter case the cadence is more developed, the divisions more rhythmical, and the music in continuous harmony. In intoning the greater part of the prayer is recited on one note and then sung by several voices in unison, the closing words of the sentence being sung to the proximate notes of the scale and in harmony.

INTOXICATION (literally poisoning, commonly restricted to poisoning by means of alcohol, for a discussion of which latter see ALCOHOLISM). Intoxication in the sense of poisoning may result from poisons having their origin outside of the human body (exogenous poisoning), or from poisons which may be developed within the body itself (endogenous poisoning, or auto-intoxication). Some of the most important problems connected with the infectious diseases concern themselves with the study of the intoxications that result from the formation of toxins by specific bacteria distributed throughout the human body during the course of a disease. From the same point of view many of the most complicated intoxications result from variations in the normal metabolism of the body. Thus, in diabetes mellitus (q.v.) there is developed an acid intoxication (diabetic coma), which is due to the inability of the body properly to neutralize by its alkaline salts the excessive amounts of acid produced as a result of the perverted metabolism of this disease. Similarly, in Bright's disease a type of intoxication (uremic poisoning) results from failure of the kidneys to eliminate poisonous products from the human body.

INTRENCHMENT, in fortification, any work, consisting of not less than a parapet

and a ditch, which fortifies a post against the attack of an enemy. As a means of prolonging the defense in a regular work of permanent fortification, intrenchments are made in various parts, to which the defenders successively retire when driven in from forward works. Bastions are ordinarily intrenched at the gorge by a breast-work and ditch, forming either a re-entering angle or a small front of fortification. An army in the field often strengthens its position by intrenchments, as by a continual line of parapet and ditch, or by a line with intervals, consisting of detached works of more or less pretension flanking each other. The war in Europe, which began in 1914, was marked by an unprecedented system of intrenchment, with shelters, dugouts, barbed wire obstacles. See FORTIFICATIONS.

INTRODUCED SPECIES. A long catalogue might be made of species of animals and plants which have been transferred by accident or design from their native country or locality to other regions. Sometimes, as in the case of salmon in New Zealand, rabbits in Australia, the European house sparrow in America and elsewhere, or Western fishes in Eastern waters, this is done by design; but in the great majority of cases the introduction is accidental and unwelcome, as in the case of the hundred and more species of injurious insects brought into the United States from foreign lands (or the fewer sent abroad from here), and the very many species of "weeds" naturalized on our and other shores. Such introductions are in the main accidental, the eggs or seeds or grown individuals passing from one region to another in ships or railway trains, or cargoes or discharged ballast; so many plants have been introduced by the latter means that botanists class the group of alien weeds as "ballast plants." See also ACCLIMATIZATION; MIGRATION OF ANIMALS.

INTROIT, in-trō'it (from the Latin *introdūcere*, to go into, to enter). An antiphon and psalm sung by the choir at the beginning of the Mass. The text of the antiphon, or introit proper, varies with the days of the ecclesiastical year, but is almost always drawn from Holy Scripture. From the opening words of these introits many Sundays derive the names by which they are popularly known, such as Laetare, Gaudete, or Quasimodo Sunday. Originally the introit was in the form of an entire psalm, preceded by an antiphon, but now it has been shortened so that only one verse of the psalm is sung, followed by the *Gloria Patri* and a repetition of the antiphon. Other names for the introit are *ingressa* (Ambrosian); *praelegere* (Gallican); and *officium* (Mozarabic).

INTROSPECTION, a method of observing and analyzing one's own mental states and processes, his thoughts and feelings. Suppose that one has a mental picture of yesterday's scene or has a feeling of impatience: if he notes this awareness and subjects it to examination, he is introspecting. This had been the psychological method par excellence until the last two or three decades. Two theoretical challenges of the validity of the method were recognized and met. One was that the very turning of a person's attention upon his feelings and train of ideas is likely to interfere with the natural flow of such processes. Another was that in the very act of attending intellectually to a present

state of mind, he inevitably changes its very character. To both challenges the answer was that introspecting properly includes much retrospect, much recalling of the immediate past; and so the particular character of the just-recalled is not essentially altered.

To use the introspective method requires long training. One error of the untrained is that he often confuses what he knows about the external source of stimulation with the description of his sensory experience as such; that is, he may be thinking too much about the coated papers he is looking at and too little about the colorful experiences he is having, just as colors.

Techniques became highly refined in the Wilhelm Wundt tradition. States of awareness were formally broken down into what were held to be their component elements. The perceptive awareness of an architectural column—to employ an example—might be analyzed first into two sensory modalities, the visual and the muscle-sense. These were further identified as possessing particular attributes of quality, intensity, duration, extensity. The visual appearance of the left-hand side might be of brighter hue, the views obtained by right and by left eye might vary in their exact spatial extent, the slight muscular strains as the observer shifts his regard from column to background and back again might become noticeable enough as he attends to them, and numerous other sensory characters might be brought out in this way. In addition, the experience as a whole might be toned agreeably, this agreeableness being of moderate intensity and diffused. From such an example it is seen that the traditional use of introspection was oriented toward analysis primarily.

An expanded method of introspection was that adopted by Oswald Külpe and his followers by which they reported their totality of experiences of the moment; and they were apparently rewarded by the discovery of other kinds of awareness than those admitted by the orthodox schools, including thought processes that went on consciously but without any imagery.

Although it has been used in a different historical context, the term "phenomenological" has much in common with "introspective." Consistently with the etymology of the word *phenomenon*, which means "appearance," *phenomenology* is the study of immediate experience at its face value and purely descriptively. The term has been adopted by several psychological and philosophical schools, which take their various departures from an attempt at "pure experience," "immediate experience." In this generic sense, phenomenology may be thought of as including the more specialized introspection.

The length of the training and the unusual character of the methods led the behaviorists to charge that the introspective procedure was esoteric. And at all events, contemporary psychologists ordinarily employ a person's introspections as strictly ancillary to the objective observing of his behavior.

JOHN FREDERICK DASHIELL,
Kenan Professor Emeritus of Psychology, University of North Carolina.

INTROVERSION, in-trō-vūr'shūn, in psychology, a characteristic style of personality adjustment in which the center of interest lies in the individual's own mental life and not in the environment or in other persons. The introvert is withdrawn, thoughtful, and deliberate in making decisions. He does not like exuberant amusements, stories of daring adventure, or activities which call for display of skills before large audiences. He does not depend for his satisfactions upon approval from others, upon a wide circle of acquaintances, or upon gay parties. He derives satisfactions from performances which meet his own expectations; from a few well-chosen friends; and from quiet, even solitary, recreation. He has what William James once referred to as "aseity"—that is, self-sufficiency.

John Milton distinguished between two types of men—one type being happy, ebullient, active in the search for associates (*L'Allegro*); the other, stable in emotions, reserved in manner, and happiest when engaged in study or in solitary contemplation (*Il Penseroso*). The ideal day which each of these men enjoyed conforms, in many ways, to popular concepts of the extrovert and the introvert. Personality inventories have been constructed to test whether one is extroverted, ambiverted (that is, midway between the extremes), or introverted, and to what degree. Such questions as these are usually included, to all or most of which an introvert would answer "Yes":

Do you often cross the street to avoid meeting someone?

Do you prefer novels or plays which analyze the motives of characters?

Would you be embarrassed if suddenly asked to be "stunt leader" at a large party?

Are you able to spend evenings at home and alone without being bored?

In company, would you prefer to listen than to be the center of attention?

Carl Gustav Jung, founder of analytical psychology, developed an elaborate and complex system for "typing" persons. First, he said that everyone has a dominant psychic attitude along the personality dimension of introversion-extroversion. This is determined by the manner in which all energies are directed, whether toward the self or toward the outer world. Secondly, there are four ways of functioning. A person may be concerned with the immediate aspects of a situation (*sensation function*); with the antecedents and the possible consequences of the situation (*intuition function*); with judgments of values (*feeling function*); or with abstract concepts (*thinking function*). There may be a harmonious relationship among the dominant psychic attitude and the four ways of functioning; then, according to the Jungian analysts, the individual would be in good mental health. A lack of balance, however, would create more or less maladjustment.

Suppose, for example, a fervent introverted reformer has disharmonies among his functions. *Thinking* might lead him to untenable opinions; *intuition* ("hunches"), then, could make his speeches incoherent and disorganized; *sensation* might cause his message to lack perspective; and *feeling* could lead him to purposeless endeavors. The Jungian analyst would be confronted by the problem of restoring the balance among these functions, a process that could take a long time. He certainly would object to the use of oversimplified inventories which are based upon a superficial and mistaken knowledge of what Jung

actually taught about introversion and extroversion.

PHILIP L. HARRIMAN.

INTRUSION. See ROCKS.

INTUITION, in-tū-ish'ūn, immediate or direct knowledge, apprehension, or understanding; awareness as if by unimpeded sight or grasp of the object, rather than reflection about it. Intuition is variously contrasted with one or more of the following kinds of indirectness or discursiveness: (1) inference or interpretation; (2) symbolism or representation by words or ideas; (3) formulation in judgment, with subject and predicate; and (4) analysis to constituents. The word is thus applied to mystical vision, to religious inspiration or illumination, to the moral sense, to acquaintance with one's self and inner states or acts, and to sensitivity to the thoughts, feelings, and intentions of other persons, as well as (generally now only by philosophers) to the purely sensory component of perception. In all these the knower is primarily passive or receptive, and the object is a particular or individual, more or less concrete, while the experience is more or less incommunicable. Philosophers, logicians, and scientists, however, speak also of intuitions of universal essences (Edmund Husserl and George Santayana, for example), and of intuitions of very general abstract truths, thus connoting sometimes the self-evidence of a principle which has become perfectly clear to the mind (René Descartes, Baruch Spinoza, John Locke, Sir William Hamilton), and sometimes the "hunch" or insight by which a formal conclusion is conceived and felt to be correct in advance of proof. The last use is common to scientific and logical writings and ordinary speech ("woman's intuition"). For a famous and distinctive philosophical doctrine of intuition, see BERGSONISM.

DONALD C. WILLIAMS,
Harvard University.

INUKAI, è-nōō-kī, Ki Tsuyoshi, Japanese journalist and statesman: b. Okayama-ken, Japan, April 1855; d. Tokyo, May 16, 1932. After graduating from Keio University, he became a correspondent and then editor of the newspaper *Hōchi Shimbun*. In 1890 he was elected to the Japanese Diet, where he served continuously throughout the remainder of his life. He held the positions of minister of education in 1898 and minister of communications in 1924–1925, and in 1929 became the president of the Seiyukai Party. On Dec. 13, 1931, he was elected premier of Japan, and his party won an overwhelming majority in the Diet the following February; however, a strong militaristic faction, already in control of Manchuria, became angered by his peaceful policy toward China and three months later caused his assassination, thus ending effective parliamentary government in Japan until after World War II.

INULIN, in'ū-lin, a chemical substance resembling starch, derived from the roots and bulbs of several plants, including *Dahlia variabilis*. A lumpy, white powder, it has a formula of $(C_6H_{10}O_5)_n$ and is used in the manufacture of diabetic bread and of fructose.

INUNDATIONS. See FLOODS AND INUNDATIONS.

INVALIDES, ān-vā-lēd', *Hôtel des*, one of the most beautiful monuments in Paris, France. It was founded by Louis XIV in 1670 as a residence for old and wounded veterans of the French armies. Opened in 1675, it accommodated 6,000 officers and men. For a while it served as a place of retirement for the aged servants of court favorites as well as the disabled soldiers, but this abuse was ended by the Comte de St. Germain in the reign of Louis XV. It is now supported by the state. The architect of the hotel and chapel was Libéral Bruant. The general design of the building, in the shape of a Greek cross, is vast and notable for its symmetry and simplicity of line, its harmonious use of space, and its many sumptuous galleries and porticoes. The dome of the chapel was built by Jules Hardouin Mansard. An elegant, magnificent construction, it is an example of classic majesty without heaviness, and sets off the gracefulness of the building. Under that high gilded dome are the tombs of the Vicomte de Turenne, the Marquis de Vauban, and Jérôme and Joseph Bonaparte, and, in the center, twenty feet below the floor of the church, the tomb of Napoleon I, whose remains were brought to France from St. Helena in 1840. Napoleon's mausoleum is surrounded by 12 colossal statues, commemorating the 12 principal victories of the emperor. The statues, the pillars, and the cornice are made of white marble.

INVAR, ĭn-vār, a trade name for an alloy containing 34 to 36 per cent nickel (the balance made up of iron), characterized by its extremely small coefficient of thermal expansion, with good strength and endurance at elevated temperatures. Because of its very small change of dimension with temperature, the alloy is used for measuring tapes, precision components for machines, and pendulum rods. The International Bureau of Weights and Measures has adopted Invar as a length standard. The high polish attainable and the corrosion resistance of the alloy are added assets.

One of the principal uses of Invar is as a bimetal. A bimetal is a composite metal, half of whose cross section consists of a metal with a high-temperature coefficient of expansion and half of a metal with a low-temperature coefficient of expansion. As the temperature changes, the difference in expansion causes the composite metal to bend. If one end of the bimetal is fixed, the curvature occurring with changes in temperature may be made to cause deflection at the free end which could operate electrical contacts. In temperature indicators, where a large deflection is desired, the bimetal may be in the form of a helical spring. When the outer end is fixed, the inner end can be attached to a shaft which will then rotate with changes in temperature. Two widely used bimetal composites with high sensitivity at room temperature are brass-Invar, and silicon bronze-Invar, the Invar serving as the low expansive side. Austenitic corrosion-resistant steel can be substituted for the copper alloys on the high expansive side and used with Invar at high temperatures where better stability and greater resistance to failure by overheating are desired.

ALVIN S. COHAN.

INVASION, ĭn-vā'zhŭn, in military affairs, the unauthorized entry of armed forces of a nation into the territory or possessions of another. When the invasion is abrupt and hasty (for ex-

ample, the German invasion of Norway in 1940) it is termed an *incursion*; when undertaken with particular violence (the German invasion of Poland in 1939) it is referred to as an *irruption*. Invasions may be undertaken (1) to conquer and absorb another nation; (2) to overthrow the existing regime and substitute a friendly puppet government; (3) to conquer territory desired for national expansion; (4) for economic gain, or to enforce economic cooperation (Napoleon's invasion of Russia in 1812 to impose acceptance of his Continental System); or (5) to assist or free a conquered ally (the Allied invasion of France in 1944). An invasion usually precipitates a war. When wars could be limited without endangering entire populations, as in the 18th century, invasions could be undertaken purely with a profit motive to annex adjacent provinces or to exact tribute. With the subsequent development of total war and its detrimental consequences for victor and vanquished alike, invasions were not undertaken with impunity. In mid-20th century, the possibility of mutual extinction through the use of nuclear weapons of tremendous power acts as a deterrent to invasion by armed forces which would precipitate a general war. Instead, the objectives of invasion are being sought by means not likely to create a formal state of war—the "cold war" with its infiltration, attempts at subversion, and its ideological struggle for the mind of man. The initiation of a formal state of war has been avoided by the subterfuge of invading with so-called "volunteer" forces—forces denied as official components of a nation's armed forces and depicted as groups of individuals volunteering to aid a friendly state (the Chinese Communist operations in Korea in 1950–1951).

VINCENT J. ESPOSITO.

INVENTIONS. Inventions are new concepts, new combinations of known elements, new techniques of action that can become an integral part of the knowledge and skills with which we can use natural resources and the forces of nature. We frequently contrast invention and discovery, but there is little gained in attempting a formal distinction between these terms. New concepts are ordinarily little more than the first step toward the construction of new apparatus. New understanding of the principles of optics led directly to the construction of compound telescopes and microscopes. The measurement of air pressure and the analysis of the vacuum led after an interval to the effective use of steam. The emergence of novelty is the important fact, not the form or level at which it occurs. In the study of inventions, however, it is necessary to recognize that the individual item of novelty is small, and that we commonly fail to distinguish between a particular invention and the long sequence of earlier inventions to which it gives new and conspicuous meaning. Thus, James Watt's conception of the condensing engine in 1765 rested upon the whole sequence of scientific and mechanical efforts that began in 1644 with Evangelista Torricelli's analysis of atmospheric pressure and the phenomena of the vacuum. Inventions are not isolated, or detached items, but steps in a coherent process of cumulative synthesis. Our science and technology are thus, the consequence and summation of our cultural history. The heritage reaches back to the preliterate cultures of the Western World, though few devices are still in use that go back to the beginnings

of cereal growing and settled agriculture, about 8000 B.C. The potter's wheel is, perhaps, the outstanding example of a device that has survived the centuries of progressive sophistication with no more than incidental modification. Massive accumulation does not begin prior to the development of science in Mesopotamia, Egypt, and Greece in the 5th and 6th centuries B.C.

Technology in Antiquity.—Our knowledge of technology in this early period rests upon archaeological evidence supplemented by treatises and literary references. We are rarely able to identify individual inventors or inventions. The water screw is commonly attributed to Archimedes (287–212 B.C.), but some writers confidently assume that it was used much earlier in Egypt, though no pictorial representation is cited. Two inventions, the force pump and the water organ, are credited to Ctesibius (300–220 B.C.), the author of a lost treatise, preserved in part by the work of his pupil Philo of Byzantium. These attributions are probably justified; both mechanisms involve important new principles which are closely related to the field of interest covered by the treatise of Philo. They are not likely to be earlier, but they may never have been built. The water wheel shown by Philo to work a chain of pots to raise water may be just a concept. The type of wheel shown cannot be identified with either of the types that came into use at the close of the pre-Christian era. The treatise contains some new concepts, some new inventions, and some descriptions of known mechanisms.

The outstanding inventions of antiquity were two types of water wheels; a number of applications of large screws; several applications of gears and worms; an array of cranes; a variety of small devices to use pressure media; and two major developments of the loom. For descriptions of these devices we are largely dependent upon the treatises of Vitruvius (fl. 27 B.C.–14 A.D.), and Hero of Alexandria (1st century A.D.).

A small water wheel was invented in Greece, probably in the 2d century B.C. It was a very simple device. Four or more paddles were attached to a shaft which turned the upper millstone. The mill could be made by any carpenter, and required little skill from the operator. We know little of the history of this mill in Greece, but it came into extensive use in northern Europe as early as the 4th century A.D. A larger mill is first described by Vitruvius, and is commonly presumed to have been invented only a short time before the composition of the treatise. This mill had a relatively large wheel set vertically in the stream. It could be used as an undershot wheel, an overshot wheel, or as a breast wheel. The power from the wheel was transmitted to the millstone by a shaft with gears, or a toothed wheel and a rundle. This water wheel came into extensive use in the 3d century A.D. in Rome itself, and in some of the provinces, notably at Arles.

Gears also appear in other mechanisms. Hero of Alexandria described a cyclometer to measure distances. The device combines gears with worm drives on axles to connect the measuring wheel on the road to the counting dial which registers the distance traversed. Gears were also applied to the control of a surveying instrument called the dioptra. No lenses were used, but the parts of the instrument were fully controlled by the gearing. Heavy-duty screws of wood were applied to wine and olive presses, and also to

a lighter model for cloth. A device for cutting wood screws is shown by Hero, though the larger screws were generally cut with hand tools.

Both Vitruvius and Hero describe cranes of various types, but there is archeological evidence of earlier use. The word for pulley appears in Mesopotamia as early as 1500 B.C., and pulley wheels of wood have been found at Nimrud (c. 900–700 B.C.). The stones for the lintels in the Greek temple at Bassae (5th century B.C.) have slots for the use of lifting devices which imply some form of crane. The pneumatic devices described by Hero embody important principles, though in antiquity they were applied to the manipulation of figurines for the amusement of spectators, or as some feature of temple service.

From archaeological sources, we know that the loom with four or more heddles and the draw loom appear in Syria shortly before the close of the pre-Christian era. The loom with heddles is presumed to be a Syrian invention, and the serge weave is certainly Syrian in origin. The draw loom, figured weaves, and the satin weave came from China.

Medieval and Renaissance Technology.—

After the fall of Rome, the history of technology was dominated by the diffusion and development of the major inventions of the last three centuries of the ancient world. New work was not urgent. However, in one field important new developments occurred. Horses and mules had been used in antiquity, but the harness was ill designed, and no successful protection had been provided for their feet. After some improvements in the breastplate, the harness for draft horses was finally perfected by the introduction of the padded collar fitted to the bones of the neck (9th century A.D.).

The invention of the mechanical clock was the greatest achievement of the Middle Ages. Water clocks were widely used in cathedrals and monasteries, and these clocks have frequently been confused with mechanical clocks, but it is now recognized that there was no mechanical clock earlier than the second quarter of the 14th century. The clock erected in Milan in 1335 is the first that can be certainly identified as a mechanical clock. Jacopo di Dondi built a clock in 1344 at Padua, and clocks were built at Modena in 1343 and at Monza in 1347. In 1348, Giovanni di Dondi began an astronomical clock that was finished in 1364. This was fully described in a treatise that is still extant. The clock built by Henri De Vick in Paris in 1370 is still in place on the tower of the Palais de Justice, though the movement was extensively repaired in 1760 by Pierre Leroy. Its original condition was described in detail by him, with good drawings. Early clocks that have survived were modified by the addition of a pendulum after the time of Christian Huygens.

The invention of printing in the 15th century is another basic achievement. We have many specimens of early printing, but our knowledge of the techniques used is incomplete. The crucial problem was to produce good type. The records are confusing, but it is clear that Johann Gutenberg's great invention was the adjustable type mold. This may have been achieved as early as 1439 at Strasbourg, and in any event at an early date after Gutenberg came to Mainz, possibly in 1448. A number of improvements in type founding were developed soon after the invention of the type mold, and some details of the press

were modified, but the primary features of the new process were established when the 42-line Bible was printed (c. 1453).

The addition of the flyer to the spinning wheel was an important invention. It doubled the output of the spinner, and opened the way to the application of power to spinning. A dated picture of 1480 shows the flyer as a device already in use. The possibility of applying power was perceived by Leonardo da Vinci, but, although his machine provided for many of the motions, one essential element in the machine was still wanting. The use of rolls was introduced by John Wyatt and Lewis Paul in 1733; there were still defects, however, which were not overcome until Richard Arkwright made small, but vital, improvements (1769).

Heavy-duty screws were more extensively used in the 15th century, and Leonardo da Vinci perceived the possibility of using long lead screws to operate machine tools. One of the notable applications of this principle was a machine to cut long screws of varying pitch. This device foreshadowed the machine tools of the 19th century, but the wooden lathes were not sturdy enough to produce accurate work. Much of Leonardo's work remained in this conceptual stage, but it was nevertheless of great importance. A number of his inventions are cited in the list that follows under the general date 1496, as the mechanical drawings are not dated, nor arranged in chronological sequence.

Rise of Modern Technology.—Benvenuto Cellini developed a screw press for stamping medals and coins (1512). This invention laid the foundations for the development of die stamping, first for coinage in France, England and Spain, and later for much flat work in gold and silver. Small rolling mills were used in preparing gold and silver for coinage. Improvements in pump construction in the 16th century made it possible to use the vacuum pump effectively. Metal fittings were used for critical features of the pump, and they began to displace force pumps. Analysis of the problems of the pump led to the discovery and measurement of atmospheric pressure. Otto von Guericke demonstrated the magnitude of these forces, and an atmospheric engine was invented by Thomas Savary and Thomas Newcomen. Watt's analysis of the performance of these engines led directly to the invention of the condensing steam engine. Modern power engineering thus rests directly upon a chain of inventions initiated by the development of pumps in the mines of Germany in the time of Agricola (1494?–1555).

The history of lathes and tool-making machinery runs parallel to the history of power machinery. Pattern turning lathes with a lead screw drive and a slide rest were invented for turning wood and ivory. In the clock and watch trades lathes were developed capable of working the nonferrous metals with accuracy. The invention of the pendulum made it essential to improve the escapement, and study of the behavior of the teeth of the escapement wheels led to a full mathematical analysis of gear teeth. John Wilkinson's boring engine, Henry Maudslay's lathe, Marc Brunel's block-making machinery, and Eli Whitney's system of interchangeable-part manufacture were the culmination of 250 years of progress in light engineering. The great tool makers of the early 19th century did accurate work in iron and steel that had been done earlier

in wood, ivory, and the nonferrous metals.

As we move into the 19th century, the scope of inventive effort can be most effectively appreciated if we deal with broad divisions of technology rather than with specific items. The individual inventions listed below will give the more important steps in the historical sequences. Power engineering was addressed to the task of developing a comprehensive set of prime movers using different sources of energy, and offering a variety of characteristics as to size and rate of revolution. In 1832, Benoit Fourneyron (1802–1867) invented the hydraulic turbine, which made it possible to use water power efficiently under an extraordinary range of conditions. The general principle admitted many variations in detail so that many alternative types of turbines were developed.

In steam engineering, the noncondensing engine was developed by Oliver Evans and Richard Trevithick. It found a wide range of uses, notably as the locomotive. Condensing engines were developed on the compound principle, with double and triple expansion. These types proved to be essential to marine use. Finally, steam turbines were invented by Carl de Laval (1882) and Sir Charles Parsons (1884); the differences in their characteristics were important as they were adapted to different uses. The whole array now provides for every need from running a cream separator to the generating equipment of a 100,000 kw central electric station. The internal combustion engines have been adapted to gas, gasoline, or oil as fuel, and also offer a wide range of sizes and types.

After a long period of modest development from the time of Benjamin Franklin to that of Thomas Edison, electricity finally became a basic form of energy. The application of electricity to the telegraph and telephone left electricity well below the level of major power engineering. The development of the dynamo and the motor opened up new potentialities, which were modestly exploited in small-arc lighting systems. With the invention of the carbon lamp (1878), the development of the central station (1882), and the successful establishment of electric traction (1888), electricity entered the field of primary power engineering. Large hydraulic turbines and the steam turbines made concentration of generating capacity highly advantageous, so that, as early as 1912, the importance of interconnected networks was perceived. After World War I large regional electrical networks began to appear in Europe and in the United States. Generalization in the production and distribution of power was largely complete in these areas by 1950. This marks the completion of a major stage in power engineering.

The importance of electrical developments in the power and light fields attracted so much attention that the development of other electrical apparatus received less notice than it deserved. The use of electricity in the fields of communication and observation seemed to be of secondary importance for the growth of the economy. This was, however, a complete misjudgment of the significance of the progress of the electrical sciences. The discovery and control of electromagnetic waves, the analysis of the cathode rays, and the comprehensive revision of the concept of the atom resulted in the most extensive development of pure science and technology that had occurred since the Renaissance.

The properties of electromagnetic waves were analyzed theoretically by James Clerk Maxwell in 1867, and the waves themselves were produced and studied by Heinrich Rudolph Hertz in 1887. Adequate techniques for general communication by wireless were achieved by Guglielmo Marconi in 1895, and a decade later great improvements in sending and receiving by the use of vacuum tubes made telephonic communication possible. The vacuum tube, as a control device, was developed from work initiated by Thomas Edison in 1885. In studying the blackening in the incandescent lamps, he inferred that carbon particles were projected in straight lines from the negative leg of the carbon filament. To prevent deposition of carbon on the bulb, he placed a metal plate in the bulb connected with the positive side of the direct current supplying the lamp. This prevented blackening, but he also observed that a current flowed across the vacuous space in the bulb. He was aware of the importance of this phenomenon as a means of regulating electrical apparatus, and he took out a patent, Oct. 21, 1884. The valve makes it possible to amplify energy at low levels into energy at high levels, so that massive apparatus can be controlled by initially weak currents or signals.

The earliest applications of the vacuum tube were in radio reception. In 1904, John Ambrose Fleming produced an incandescent lamp receiver based on studies of the Edison effect. Practical transmission and reception by this technique began with Lee de Forest's lamps of 1906 and 1907, to which a third grid had been added. Structural improvements, notably by Edwin Howard Armstrong in 1912 and 1913, established the vacuum tube firmly in the radio industry. The great extensions in the use of electronic devices in recent years received their initial impulse from the development of electronically controlled computing machines during World War II. The history of these machines is not closely associated with the mechanical computing machines of the earlier period. The simpler adding machines, beginning with Blaise Pascal in 1642, were adaptations of clockwork that had little significance for the future. The ambitious project of Charles Babbage (1823-1833) for the computation of logarithms showed clearly the limitations of purely mechanical principles. The geared wheels required more energy than could be practically supplied to the machine, and the rate of operation was too slow. The technique of supplying information by means of punched cards was, however, of early origin. The immediate source of this technique was the tabulating machine developed by H. Hollerith in 1885. His system was suggested by the use of cards in the Jacquard pattern weaving loom. The card was first used by M. Falcon in a rudimentary loom in 1736. It was fully perfected by Joseph Marie Jacquard in 1801. The developed electronic machines use magnetic tape as the ultimate means of giving directions to the machine, but the punched cards remain as an intermediate stage in the setting of problems for the machine.

The electronic computing machines fall into two general types: the digital computers, and the differential analyzers. The first type is capable of handling the problems of industrial control or office work. The differential analyzers are essential for certain kinds of scientific problems, and would supplement the simpler machines in some commercial work. The application of power

in the industrial field had long since prepared most of the mechanical appliances for the more extensive controls made possible by the electronic technique, but, with automation, it was possible to move from one train of mechanism to another without the intervention of an operator. For the control of processing, photoelectric cells or radioactive isotopes are used. It is, thus, possible to maintain more accurate conformity to standards than would be achievable by earlier methods of sample inspection.

The analysis of atomic structure has opened new vistas in science and technology. Since the Geneva conference on the peaceful uses of atomic energy, much progress has been made. With the achievement of "breeding" in 1953, the development of atomic energy for commercial use became practical. The British reactor at Calder Hall began to turn energy into the power system in 1956, and in that year reactors were under construction in the United States, Europe, and Soviet Russia.

New Environment of the Inventor.—The development of large research organizations has changed the environment of the inventor. Some writers have presumed that the essential characteristics of inventive work have been changed. There seems to be less inspiration, and, as Edison once said, more perspiration. However, invention has not become a laboratory process in the sense of being achievable at will. The essential features of such group work are almost a century old. Sir Henry Bessemer, at an early age, decided to become a professional inventor. It was to be a career. With less deliberation, perhaps, Edison found that his electrical inventions would use all his time, so with the receipts from the printing telegraph he established the laboratory at Menlo Park. The work on the incandescent lamp was done here under conditions that differ only in degree from those created by the research enterprises during World War II for the development of the work on radar and atomic fission.

The distinctive feature of these achievements is the organized, step-by-step development of the implications of a single phenomenon, such as the echo of radar waves or the spontaneous fission of uranium. Under modern conditions an organized effort results within a short time in a sequence of inventions comparable to the historical sequence from Torricelli's measurement of atmospheric pressure in 1644 to the invention of the steam turbines by de Laval and Parsons in 1882 and 1884. Work begins with an accumulation of observations, and at this stage much is done that hardly rises to the level of inventive activity, though the effort to make new kinds of observations requires the invention of scientific apparatus. The study of the atmosphere resulted almost at once in the invention of the barometer and the thermometer. In this early period, engineering skills were not mature enough to make it possible to condense the process of invention in time.

Basic scientific work in nuclear physics preceded the establishment of the Manhattan Project (q.v.), but the underlying work was done in laboratories and involved the invention of new apparatus. The spontaneous fission of uranium was known, and the analysis of the phenomena of fission was far advanced. The possibility of producing energy for commercial use was recognized, but the exploration of that potentiality was de-

liberately postponed. All three preferred approaches to the bomb were utilized. Each step in the highly concentrated work of the Manhattan Project can be matched in the history of the steam engine. It is not easy to see how the atomic program could have developed without the financial support of the government on a large scale, but this provision of funds does not affect the character or the quality of the inventive process. The complete achievement is the result of drawing together a great number of individual items resting on highly original acts of insight. If the records are complete, all the individual steps and personalities can be identified. The group effort concentrated in a short period of time does not

differ in essentials from a diffused effort over a long period.

¹American citizen since 1945.

INVENTORY, in'-vën-tō-rī, an itemized list of goods, chattels, debts, credits, and sometimes real estate, usually with the corresponding actual or estimated value attached, made to fulfill legal requirements or as a routine business procedure. The "benefit of inventory" originated in Roman law, to protect an heir from liability for debts and claims beyond the value of the estate inherited. Today executors or administrators are required, as one of their first duties, to file an inventory of the property in their charge in order to secure it to the persons entitled to it. Guardians are also required to make inventories of estates held in trust for their wards, and bankrupts or insolvents have to file a list of their property, debts, and liabilities.

INVERCARGILL, in-vēr-kär'gil, city, New Zealand, on South Island. It is the capital of Southland County, in Otago Provincial District, on an inlet of Foveaux Strait, 110 miles southwest of Dunedin. Invercargill is the rail, trade, and commercial center of an agricultural and dairying area. Included among its manufacturing establishments are flour and wool mills, breweries, foundries, and timber works. Although it has a good harbor, most of the shipping occurs at nearby Bluff. It was settled in 1857. Pop. (1956 est.) 34,293.

INVERCHAPEL, in-vēr-chăp'ěl, 1st BARON (ARCHIBALD JOHN KERR CLARK KERR), British

diplomat: b. Lanarkshire, Scotland, March 17, 1882; d. Greenock, July 5, 1951. He entered the diplomatic service in 1906, and after four years in the Berlin embassy was transferred to Buenos Aires, Argentina, and a year later to Washington, D.C. In 1913 he was sent to Rome, and after the outbreak of World War I to Teheran, Persia (Iran), where by 1916 he was in charge of the legation's commercial affairs. At his own insistence he was allowed to enlist in the Scots Guards, and saw active fighting in World War I as a private. In 1919 he resumed his diplomatic career, serving successively as British minister to Guatemala (1925-1928), Chile (1928-1931), and Sweden (1931-1935), and then as ambassador to Iraq (1935-1938). In 1938 he was appointed ambassador to China, which was then engaged in war with Japan; his diplomatic talents were well displayed in the difficult task of reaffirming Britain's friendship for the former while at the same time not provoking war with the latter. He was sent to Moscow as ambassador in 1942 and remained there four years, participating in the Cairo, Teheran, Yalta, and Potsdam conferences as adviser to the British representatives. He went to Java on a special mission in January 1946, endeavoring to find a solution to the Netherlands-Indonesian dispute, and on his return to London was made a baron, taking the title of Lord Inverchapel of Loch Eck. From June 1946 until February 1948 he was ambassador to the United States.

Philip Gendreau

A 19th century castle rises above Inverness, on the river Ness.

INVERNESS, ĭn-vēr-nēs', town, Nova Scotia, Canada, in Inverness County, on the west coast of Cape Breton Island, 55 miles west of Sydney. Mining, lumbering, fishing, and agriculture are the chief industries of the area. There are fine bathing beaches, and hunting and fishing are popular in the Margaree district. Gaelic is spoken extensively by the descendants of the original Scottish settlers of the region. The town, on a branch of the Canadian National Railway, is picturesquely situated on the shore of the Gulf of St. Lawrence. There are coal mines in the vicinity, and it is a coal shipping port. A deep-sea fishery operates from the harbor. The town was incorporated in 1904. Pop. 2,109.

INVERNESS, burgh, Scotland, the county seat of Inverness-shire (q.v.), situated at the mouth of the Ness River, where Beaully and Moray firths join, at the head of Glen More, one mile from the northeast end of the Caledonian Canal. It is a commercial and rail center and seaport, and is often called the capital of the Highlands. Chief manufactures are woolen and tweed goods, leather, and whiskey, and there are sawmills, iron foundries, railway shops, and shipyards. The town is noted for the beauty of its environment and its fine buildings. Although it is modern in appearance, it has a long history and was once the capital of the Picts, whom St. Columba visited here about 565 A.D. to convert them to Christianity. Macbeth's castle, which stood in Inverness, was razed by Malcolm III in 1057 to avenge the murder of his father, Duncan I. A new castle was built by Malcolm or his son David I (r. 1124-1153), and William the Lion (r. 1165-1214) made the town a royal burgh.

Oliver Cromwell built a fort in Inverness in 1652, but only a portion of the ramparts remain. The town cross dates from 1685, and at its base stands the ancient stone of Clach-na-Cudainn (Stone of the Tubs). The old castle was partially destroyed by Robert the Bruce in 1307 and finally blown up in 1746 during the Jacobite uprising. A modern castle, now used for county offices, was built on the site in 1835. Pop. (1961) 29,773.

INVERNESS-SHIRE, ĭn-vēr-nēs'shīr, county, Scotland, bounded on the west by the Atlantic Ocean, on the north by the County of Ross and Cromarty, on the northeast by Nairn and Moray, on the east by Banff and Aberdeen, on the south by Perth, and on the southwest by Argyll. It is the largest county in Scotland, 4,211 square miles in extent, and includes some of the islands of the Inner and Outer Hebrides. A large part of the surface is broken and mountainous, and the highest peak in Great Britain, Ben Nevis, which rises 4,406 feet, is in the southwest. Other high peaks are found in the Cairngorm and Monadhliath Mountains. The county is divided by a geological fault which runs from southwest to northeast, called Glen More or the Great Glen, whose lochs, Ness, Oich, and Lochy, are joined in a navigable waterway, the Caledonian Canal (q.v.). There are over 200 lochs and many rivers, the longest being the Findhorn, Spey, Nairn, and Dulnan. Only a small part of the land is cultivated; fishing and grazing are the chief occupations, and there is quarrying of slate, granite, and quartz. Industries include spinning and weaving of woolen goods, brewing, distilling, sawmilling, shipbuilding, chemical

manufacture, and aluminum processing. The chief towns are Inverness (q.v.), Fort William, and Kingussie. Gaelic is spoken by over 23,000 persons. Inverness was occupied by the Picts in Roman times, and was incorporated into the kingdom of Scotland by Malcolm III (d. 1093). The clan system attained its greatest power here, but broke up after the defeat of Charles Edward Stuart (Bonnie Prince Charlie) at the Battle of Culloden Moor in 1746. Many remnants of prehistoric cultures, such as lake dwellings and stone circles, are scattered throughout the county, as well as towers and forts built by the Picts.

In the literature concerning Scottish legend and history, Inverness-shire occupies a considerable place, forming the background for the story of the Bruce and the Jacobite rising of 1745. Sir Walter Scott's poem, *The Lord of the Isles* (1815), and his novel, *The Legend of Montrose* (1819), may be especially noted, while his diary of a yachting tour has much about the island parts of the country. These same islands inspired the famous anonymous poem, *From the Lone Shieling*, and much about them and the mainland will be found in Dr. Samuel Johnson's *A Journey to the Western Islands of Scotland* (1775). Robert Burns (1759-1796) records his associations in his song on *The Lovely Lass of Inverness*. Pop. (1951) 84,924.

INVERSION, ĭn-vûr'shûn, a change of order whereby the first becomes last and the last first. *In rhetoric*, it signifies a reversal of the natural order of words for the sake of euphony, emphasis, or the like; also the turning of one's own argument against him by an opponent in discussion. *In chemistry*, it means a change in molecular structure which is usually induced by fermentation or by heating with a dilute acid, as in the case of starch or sugar. Thus starch and dextrine are changed into glucose, cane sugar into invert sugar, and maltose into glucose. *In geology*, inversion is the overturning or folding over of strata by an igneous agency, so that the order of their succession seems reversed. *In mathematics*, it is the operation of changing the order of the terms, so that the antecedent takes the place of the consequent and the reverse, in both couplets. Thus, from the proportion $a : b :: c : d$, we have, by inversion, $b : a :: d : c$.

In music, inversion is the transposition of certain phrases having a common root, as: (1) the change of a chord by making one of the inner notes act as a bass note, by which means as many inversions can be made as there are actual notes in the chord, not counting the root, the harmony in such inversions remaining the same, though the order of component parts is changed; (2) the alteration of intervals by making that which was the upper note the lower, and the reverse, the inversion of an interval within the octave being readily found in the difference between the number 9 and the interval known; or (3) the alteration of a subject produced by inverting the intervals of which it consists.

INVERSNAID, ĭn'ver-snâd, village, Scotland, in Stirlingshire, on the northeast bank of Loch Lomond. Nearby on the lake shore is Rob Roy's Cave, where Robert Bruce hid after his defeat by the English at Methven (1306). Here also William Wordsworth met (1803) the lass celebrated in his poem *The Highland Girl* and later also in *Three Cottage Girls*.

INVERTASE, ĭn-vûr'tās, or **INVERTIN**, ĭn-vûrt'ĭn, an enzyme occurring in many fungi, notably in certain yeasts (for example, the saccharomyces), and also in the seed plants. It transforms cane sugar into a mixture of dextrose and levulose; this mixture being called invert sugar because it turns the plane of polarized light to the left, while the cane sugar from which it is obtained turns it to the right. It has sometimes been held that a yeast cannot invert cane sugar except by secreting invertase; but *Monilia candida* effects the inversion, and yet produces no invertase. In this case the action is probably due to some other enzyme, hitherto unidentified. Invertase probably plays a very important part in vegetable chemistry. Like other enzymes, it can apparently perform an unlimited amount of chemical work, without sensible diminution of its own substance. Invertase is most active at a temperature of from 120° to 140°F., and in a slightly acid medium. It has been isolated in the form of a powder. See also **ENZYMES**.

INVERTEBRATES, ĭn-vûr'té-brâts, a collective term for those divisions or phyla of the animal kingdom that lack a vertebral column (backbone) or the forerunner of the backbone, the notochord, used to contrast with the highest phylum of the animal kingdom, the Chordata, which possess either a vertebral column (the vertebrates) or a notochord or both. The distinction between invertebrates without an internal skeleton of cartilage or bone and the vertebrates with such a skeleton was first recognized by the chevalier de Lamarck about 1800, but many years elapsed before certain groups of animals without such a skeleton were recognized as possessing a notochord and hence were aligned with the vertebrates to make the phylum Chordata. The name Invertebrata is not used as a taxonomic category because the invertebrates comprise some 20 phyla, each of which is coordinate with the phylum Chordata, and because these phyla show no close relationship to each other, but the term "invertebrates" is in constant use among zoologists in the collective sense mentioned.

INVESTIGATION, Criminal, ĭn-vēs-tĭ-gā'shûn. Criminal investigation is a field, separate and distinct, with its own specialized methods and techniques. The vital importance of crime to the national life has necessitated the development of investigative techniques which could make available evidence to identify the guilty and to exonerate the falsely accused.

The field of criminal investigation in the United States has been shaped by the democratic tradition of the nation. The law-enforcement officer, in investigating crimes, must locate evidence which can be introduced in a court of law. He must conquer the criminal by superior investigative ability and techniques, operating at all times within the realm of the law. The rights of every individual, even of the criminal himself, must be scrupulously observed. The peace officer's powers are limited, defined and continually scrutinized by the courts.

The judicial system of the United States, likewise, has affected the techniques of modern criminal investigations. The law-enforcement officer is the investigator, not the prosecutor. He does not, on his own initiative, authorize or decline prosecution, express recommendations or make evaluations. This duty belongs to the

prosecutor who, if the case goes to trial, will present in court the evidence secured by the investigator. The investigating officer, of course, may testify in court—not concerning his personal opinions or feelings, but the facts as determined through his inquiries. These requirements demand that the criminal investigation be impartial and objective, the facts obtained without color or bias.

Criminal investigation, of course, is a separate field only in reference to the development of specialized standards and a professional code of conduct. In reality, the investigation of crime is closely related to, and dependent on, many fields of human endeavor. The criminal, in preying on society, touches many phases of life. He is, unfortunately, universal in nature, appearing, in some shape or form, in practically every profession or occupation. Law enforcement, in order to meet his challenge, must combat him on his own ground. If the thief, for example, has utilized an acetylene torch in a burglary, law enforcement must familiarize itself with acetylene torches—this process might provide valuable clues. Or in other instances the investigating officer might be required to learn something about the manufacture and packaging of shoes, the mining of copper, the manufacture of steel, the building of model trains. Wherever the criminal operates, law enforcement too must operate—and draw fully upon the knowledge and technical know-how of the component elements of society.

Science.—In its many ramifications, science has become an integral part of criminal investigative work. Metallurgy, toxicology, serology, firearms identification, hairs and fibers, petrography, document examination, spectrography: these facets of science are rendering yeoman service, day after day, to criminal investigators. A scrap of paper, a broken lead pencil, a chip of paint, a tangled thread—these items, under the enlightening glow of science, may reveal the clue which will solve the case. Science gives precision, objectivity and perspective to the peace officer.

The FBI Laboratory, for example, examines each year thousands of pieces of evidence for America's law enforcement agencies. The Laboratory, which is equipped with the latest scientific instruments, is staffed with highly trained technicians, each an expert in his particular field. Science today is highly specialized. For law enforcement to benefit, directly and indirectly, from every aspect of science, expert technicians must be used. Specimens range from bicycles to baby carriages, specks of dirt to fraudulent checks, a rusty firearm to a poison pill. The entire sweep of scientific knowledge, a sweep which each year is becoming greater, is being brought to bear in behalf of the scientific investigator.

The impact of science upon criminal investigations may be illustrated by citing a few specific examples:

The analysis of body fluids (serology) is an important adjunct of the investigation of crimes, such as murder, assault and hit-and-run accidents. The most frequent examination of this type is to determine the presence of blood. If blood is confirmed, additional tests are run to ascertain whether the blood is human or animal. If animal, the type of animal can be determined through the use of sera prepared in the FBI Laboratory. On the other hand, if the blood is human, the technician can determine the blood group of the person from whom the blood came. A suspect

may claim, in reference to stains on his clothes, that they are bloodstains of a dog or some other animal or that they came from his own blood, resulting from a nosebleed or an injury. These chemical analyses, though not providing a positive means of identification, help substantiate or disprove alibis advanced by the suspects.

Another application is in the field of petrography, which includes the study of crystalline substances, soils, and minerals. The Laboratory expert, through the use of the petrographic microscope, which utilizes polarized light, is able to examine soil samples, identify their contents, and compare them with other samples obtained at the scene of the crime or elsewhere in the course of the investigation. The examination of dirt adhering to a suspect's shoes or in his trouser cuffs may be helpful in disproving or verifying an account of his whereabouts at a particular time, or in furnishing circumstantial evidence indicating that the suspect had been at the scene of a crime. Likewise, examination of a suspect's or victim's clothing may reveal the presence of mineral matter or industrial dust, which, upon analysis, may furnish data regarding his occupation or environment.

Science has enabled the criminal investigator, for example, to make dyes, which are associated with many objects of everyday life, such as clothing, plastics, wood, and inks into firm and dependable allies. The FBI Laboratory analyzes dyes by means of a spectrophotometer. This instrument, which allows the various colors of the spectrum to pass, one at a time, through the dye, which has been placed in solution, records in graph form the special characteristics of the dye. These graphs serve as ready references to identify dyes submitted in the future to the Laboratory.

In still another aspect of criminal investigation, that is, the analysis of documents, science has come to the aid of the law enforcement officer. The altering, forging and illicit issuance of checks represent today a major problem for every police department in the nation. The FBI Laboratory is able, through various chemical and mechanical devices, to identify a great percentage of the fraudulent checks which are submitted. Ultraviolet light brings forth erasures. Latent fingerprints can be developed, and through the operation of the National Fraudulent Check File numerous professional confidence men can be identified. This file, which contains many thousands of fraudulent checks, is composed of a number of sections. Checks are filed according to the method of preparation, for example, by handwriting, hand printing, and mechanical methods of preparation, such as typewriting and checkwriting. Each fraudulent check received is searched through the appropriate section of this file. If an identification is made the submitting agency will be furnished not only with background information about the individual involved, but also, if available, his arrest record and photograph. In many instances the subject is already in custody, and the contributor will then be informed as to the individual's location. If the fraudulent check cannot be identified, a photographic copy is placed in the file for comparison with other checks subsequently submitted for examination.

The National Fraudulent Check File is illustrative of the role which standard comparison files today play in criminal investigative work. These files contain specimens of known standards

which are used for comparison with unknown material submitted. Time after time, through these comparisons, identifications are effected. The FBI Laboratory, for instance, maintains such files, among others, as the Rubber Stamp File, Paper Watermark File, National Automotive Paint File, Shoe Print File, and Tire Tread File.

In the Tire Tread File the FBI Laboratory has attempted to keep currently on hand the blueprint specifications of tread and side-wall designs produced by tire manufacturers throughout the country. An investigating officer who finds what appears to be a significant tire tread at the scene of a crime can photograph it, make a sketch drawn to scale, and then make a plaster cast of it. When these are sent to the FBI Laboratory, examiners can frequently identify the tread as a particular brand and give the contributor valuable investigative information as to the size, brand, manufacturer and distributor of the tire which made the questionable tread. The identification can be made more readily from a good plaster cast than from photographs or sketches; and a good photograph is, of course, better than a sketch. The FBI's Tire Tread File also contains retread and recap designs currently in use. Although any design may be reproduced in recap or retread work, it is still frequently possible in the Laboratory to tell whether a print was made by a recapped or retreaded tire. Moreover, many retreading and recapping companies develop original designs, some of which are peculiar to certain localities and readily identifiable.

Science admittedly has greatly affected criminal investigations. However, the significance of science must be gauged, not in the past, but in the future. In the years ahead science, with ever increasing speed and accuracy, will tear away the shrouds of darkness, doubt and uncertainty. The unsolved case of today will become, with the aid of science, the solved case of tomorrow. The law enforcement officer, to keep abreast of the criminal, must constantly utilize the latest developments of science.

The FBI Laboratory, in this connection, is carrying on research programs designed to elicit new scientific applications and techniques. The latest scientific equipment is being brought to bear on investigative work. For example, the assistance rendered to scientific crime detection by the FBI Laboratory has recently been immeasurably increased through the operation of the electron microscope. This instrument, which has ten times the magnification of a high power light microscope, has enabled the FBI Laboratory to make examinations of evidence which previously had been impossible.

The electron microscope embodies an entirely new approach in the field of magnification. The use of light waves and glass lenses, necessary requirements of the ordinary microscope, are eliminated in favor of electrons, operating in a vacuum and passing through magnetic lenses. This process enables the FBI Laboratory to obtain magnifications of approximately 22,000 times, which may be increased, by use of photographic enlargements, to 100,000 times. The examiner, thereby, is capable of making a more detailed and exhaustive analysis.

The FBI Laboratory is able through the electron microscope, not only to examine more closely and extensively specimens of evidence but, by means of an electron diffraction attachment, to

determine the identity of very minute unknown substances submitted for examination. The diffraction attachment creates a diffraction pattern, similar in appearance to a series of concentric circles, which, when studied, reveals the nature of the substance in question. This feature of the electron microscope will make available to law enforcement officers investigative clues previously inaccessible to them.

The electron microscope is symbolic of what science can do for law enforcement. This instrument, though only in its infancy as applied to criminal investigations, offers unlimited possibilities.

Fingerprints.—For many years fingerprints have played an invaluable role in criminal investigative work. Man for centuries has utilized various systems of identification, such as branding, tattooing, distinctive clothing, photography and body measurement (Bertillon system). These systems, without exception, have not produced completely desirable results. Only fingerprinting, of all the methods of identification, has proved to be both infallible and feasible.

The science of fingerprinting for identification purposes is based upon distinctive ridge outlines which appear on the bulb on the inside of the end joint of the fingers and thumbs. These ridges have a definite contour and appear in several general pattern types, each with general and specific variation of not only the pattern but also the size and thickness of the ridges and the size and spacing of the pores. The outlines of these ridges appear most clearly when inked impressions are taken upon paper, so that the ridges are black against a white background, caused by the failure of the ink to fill the depressions between the ridges. Impressions may also be made with blood, dirt or the greasy substance emitted by the sweat glands through the ducts or pores which constitute their outlets. The background or medium may be paper, glass, porcelain, wood, wax, putty, silverware, or any smooth, nonporous material.

Criminal identification by means of fingerprints is one of the most potent factors in obtaining the apprehension of fugitives who might otherwise escape arrest and continue their criminal activities indefinitely. The peace officer is enabled not only to locate dangerous and badly wanted criminals, but to secure complete and accurate information about a prisoner's previous criminal history and to solve cases which previously had baffled the best investigative techniques.

The FBI's Identification Division, founded in 1924, possesses the largest collection of fingerprints in the world. At present over 114,000,000 fingerprint cards are on file. They are divided into the criminal and noncriminal files. The criminal files contain roughly 19,000,000 sets of prints, representing over eight million individuals. The non-criminal, or civil identification files, account for more than 80 per cent of the fingerprints. They contain the fingerprints of members of the armed forces, government employees, individuals who were fingerprinted while applying for jobs in defense plants during World War II, and persons who voluntarily have had their fingerprints recorded as a permanent means of identification. This latter group includes private citizens, club members, Boy Scouts, and others interested in the science of fingerprinting.

The Identification Division of the FBI has

steadily increased in size and effectiveness over the years. In 1924, at the time of its founding, the Identification Division consisted of 810,188 fingerprint cards. These cards represented a consolidation of the fingerprint collections of the National Bureau of Criminal Identification, sponsored by the International Association of Chiefs of Police, and the Leavenworth Penitentiary Bureau. In its first year of existence, the Identification Division received and handled 104,660 fingerprint cards, a daily average of less than five hundred. By the end of the 1942 fiscal year, fingerprint cards were coming in at the rate of over 114,000 a day and the total number on hand rocketed to nearly 43,000,000. The peak year for the Identification Division was 1943, when a total of 28,733,286 fingerprint cards was received. This great avalanche of cards resulted from the wartime activities of the nation. In the 1949 fiscal year, a total of 3,508,480 cards, or a daily average of 13,867, was received.

The effectiveness of the Identification Division has increased with the volume. In the 1925 fiscal year, when less than a million prints were on file and fewer than five hundred records a day were being received, 22.4 per cent of all arrest fingerprint cards received were identified. In 1949, with over 112,000,000 prints on file, this percentage had risen to 73.68.

Fingerprints, day after day, are performing feats of accomplishment for the peace officer. A set of fingerprints received by the Identification Division in the morning may result in the apprehension of a fugitive before nightfall. In February 1950, for example, the Identification Division identified 841 fugitives and maintained notices in its files on a total of 82,893 wanted persons.

The Identification Division serves as a national clearinghouse for fingerprints in the United States. In addition, through the international exchange of fingerprints criminals who have fled across national boundaries can be identified and located. The FBI in the 1949 fiscal year maintained an exchange service with 79 foreign countries and territorial possessions. A total of 13,975 fingerprint records were exchanged. The FBI succeeded in identifying, with previous records, 23.89 per cent of the fingerprint cards received from outside the country. Approximately eleven (10.75) per cent of those transmitted from this country were identified by the recipients with records previously on file.

Fingerprints serve, in addition to their criminal functions, many humanitarian purposes. For example, they aid in the location of missing persons, frequently absent from their homes for many years; the identification of amnesia victims; identification of mutilated bodies of servicemen killed in action and unidentifiable by any other means; the determination of the identities of victims, otherwise unidentifiable, of airplane crashes, railroad wrecks, or disasters by fire, explosion and accident.

Personnel Training.—Criminal investigations, in the final analysis, depend upon the men who perform them. The latest scientific equipment can be available, the most complete system of records in operation, but unless the employees in every position—administrator, supervisor, investigating officer—possess technical know-how and training, the quality of investigations will be low. The training of the criminal investigator, in present day law enforcement, is an item of the most extreme importance.

Law enforcement, unlike that of 25 years ago, is today a profession which must handle many complicated and involved problems. The peace officer often is required, with but a few seconds' notice, to conduct a crime scene search, perhaps at the site of a murder, the hideout of a bank robber, or at the locale of an extortion payoff. He must be able to handle, with dispatch and precision, the problem at hand. The evidence, an hour, even ten minutes later, may be moved or destroyed. Witnesses will have disappeared. The law enforcement officer must possess thorough training in criminal investigative techniques, training which he can apply instantly and efficiently.

Trained law enforcement personnel is vital, not only for the solution of criminal cases, but for the protection of the general public. The peace officer, among many other things, must be meticulously schooled in the use and maintenance of firearms. He carries a hand weapon. This gun, in untrained hands, can wreak terrific damage on innocent individuals. The law enforcement officer must know safety precautions, the correct way to shoot the weapon, where and in what cases to fire. Indiscriminate and irresponsible gunfire by law enforcement is indefensible. The trained officer will use the weapon, and other features of law enforcement, with a very minimum of risk, for the protection of society.

Every efficient, up-to-date law enforcement agency will have, in some form or other, personnel training programs. New recruits must be taught the rudiments of law enforcement; experienced officers must keep abreast of new developments. Training classes enable the group to share and benefit by the experiences of others; to learn the proper methods of handling scientific equipment; to know in what ways other law enforcement agencies and officers can assist. The successful criminal investigator blends individual initiative and skill with group knowledge and technical know-how.

The FBI, for example, conducts a 14-week training school for new Agents. These men, before they are assigned to actual investigative work in the field, learn the correct techniques and methods of operation: firearms, crime scene searches, fingerprints, laboratory work, mechanics of arrest, report writing. They are given both classroom instruction and practical demonstration work. The training classes are designed to equip them to meet the actual problems which they will encounter in investigative cases. When these Agents leave the school, however, their training does not stop. Approximately every two years they return to Washington, D. C., for a two-week refresher course, where they are acquainted with the most recent developments in law enforcement work. In between these in-service training classes the Agents are given training at regular intervals in their offices of assignment.

The FBI, through the FBI National Academy, has attempted to assist in the training of local police officers. This school, founded in 1935, is designed to train selected peace officers to be police instructors and executives. These men are given a twelve-week training course, which includes instruction in such subjects as traffic control, police organization and administration, investigative techniques, firearms, the operation of police laboratories, and fingerprints. The final two weeks are devoted to specialized topics which

afford the individual officer an opportunity to study particular fields most applicable to his department. There is no charge for the training by the FBI. The student must pay only for his travel and personal living expenses while in Washington, D. C.

In addition, the FBI, in 1949, participated in 2,509 local police training schools. These schools provide, on a local basis, training of the type offered in the National Academy to law enforcement officers throughout the nation. The initiative in setting up schools is taken by the local agencies and the FBI participates only upon specific request. Normally most of the instruction is given by FBI Agents and FBI National Academy graduates.

To perfect a new technique of criminal investigation is not enough. This information must be transmitted to the rank and file of law enforcement. The success of criminal investigations is dependent on the investigating peace officer making science, fingerprints, and other techniques work for him. And to accomplish this, to translate theoretical knowledge into practical application, is the work and responsibility of the training program.

Each criminal case presents different problems. The key of solution in one case, perhaps fingerprints, document examination, firearms identification, spectrographic analysis, will not necessarily solve another case. Crimes may appear, from original observation, to be identical, but, almost invariably, intensive investigation will reveal that they are different, usually much different. The same criminal, or gang, specializing in a particular type of violation, will approach the problem differently, leave different clues, make dissimilar getaways. A murder, to the criminal investigator, is not a murder to be investigated like all other murders. The officer, drawing from general principles of investigative procedure, must, in each instance, apply the key which appears most likely to solve the case.

The criminal investigator has today at his disposal powerful weapons of crime detection. Each day his abilities, through development of new techniques, are being increased. But in the final analysis the esprit de corps of the investigator, the will to do the job, is the most potent tool in the hands of law enforcement. The very best tools, handled by the half-hearted officer, become rusty and dull. The alert investigator, even with inadequate equipment, can do good work. Capable personnel supplied with adequate working tools—this is the only way the quality of criminal investigations can be maintained at a consistently high level.

J. EDGAR HOOVER,

Director, Federal Bureau of Investigation.

INVESTITURE, the act of investment implying the right to give possession of an office, honor, benefice or manor. In the mediaeval or feudal law, it was the open delivery of a feud or a right to lands and hereditaments, by a lord to his vassal, thus, by external proof, affording evidence of proprietorship. To use the words of Blackstone, "Investitures, in their original rise, were probably intended to demonstrate, in conquered countries, the actual possession of the lord, and that he did not grant a bare litigious right, but a peaceable and firm possession. At a time when writing was seldom practised, a mere oral gift, at a distance from the spot that was

given, was not likely to be long or accurately retained in the memory of by-standers, who were very little interested in the grant." For this reason investiture was performed by the presentation of some symbol to the person invested, as a branch of a tree, etc. In the primitive church, after the election of a bishop, and his consecration, the early Christian emperors claimed a right of confirmation. Charlemagne is said to have introduced this practice, and to have invested the newly consecrated bishop by placing a ring and crozier in his hands.

The custom, however, existed, nor does it appear to have been objected to or opposed during the lapse of two centuries from his reign. The disorderly state of Italy, which succeeded the death of Charlemagne, frequently interrupted the exercise of this right by the Carolingians; but even so late as 1047, when the empire had passed to another line, Henry III received an explicit admission of his prerogative, and repeatedly used it. The investiture in the lesser sees followed as a matter of course. Alexander II issued a decree against lay investiture in general, which was revived by Gregory VII (Hildebrand), who, having succeeded in annulling the prerogative of the emperors to nominate or confirm popes, sought to disjoin entirely the ecclesiastical from the civil rule. It was not, however, until the papacy of Calixtus II, in 1122, that the question was terminated, as it appears, materially to the advantage of the Holy See. In France, even under the papacy of Hildebrand, the right of investiture does not appear to have been made a subject of open quarrel. In spite of the protests of the Holy See, the kings exercised the power, but at length relinquished the presentation of the ring and crozier, and contented themselves with conferring investiture by a written instrument, or orally, upon which they were left in peaceable possession of the power. But in England Paschal II was engaged in a contest little less fierce than that which he maintained with the emperor. Anselm, the primate, refused to do homage to Henry I for his see. The king seems to have asserted an unqualified right of investiture, which the pope, who was appealed to, as unqualifiedly denied. After a protracted struggle, and continued threats of excommunication, the controversy ended in England, as it did afterward in Germany, by compromise. Paschal offered to concede the objections against homage provided Henry would forego the ceremony of investiture. To this he agreed (1107).

INVESTMENT BANKS AND BANKING. See BANKS AND FINANCE—24. *Investment Banking.*

INVINCIBLES, an Irish secret society of 1882, an off-shoot of the Fenians (q.v.). One of the objects of the Invincibles was, to "remove" or assassinate government officers or others who might incur the displeasure of the association or its leaders. On May 6, 1882 the society succeeded in "removing" Lord Frederick Cavendish, who had just arrived from England as Secretary for Ireland, and Thomas A. Burke, the under-secretary, in the Phoenix Park at Dublin. The plot was directed against the lat-

ter, but because Cavendish was there he also was stabbed fatally by the nine Invincibles making the assault. The trial of those charged with complicity in the murders began on Feb. 20, 1883; five were condemned to death, and the others received prison terms. The chief witness for the prosecution was James Carey, a leader of the Invincibles since 1881, whose life was threatened because he informed on the group. He and his family were secretly placed on a ship bound for South Africa, but the Invincibles learned of the plans and succeeded in getting one of their members aboard. Carey was shot dead by this man on the ship near Natal on July 29, 1883.

INVOICE, ĭn'vois, a list or bill of goods; a detailed statement of merchandise shipped to a consignee. Invoices generally list the quantity of material, its price, and the charges incurred for shipping. An invoice often accompanies a shipment of goods along with the bill of lading from the consignor to the consignee. It is not a document of title or a contract of sale, and it has no value in law other than as a memorandum. When goods are shipped to foreign countries, consular invoices must frequently be signed by the consul of the country of destination.

INVOLUCRE, ĭn'vô-lŭ-kēr, in botany, a group of bracts surrounding flowers or fruit and occupying a place on the floral axis beneath the cluster of blooms or fruit. Involucres are particularly characteristic of the Compositae.

INVOLUTE. See EVOLUTE.

INVOLUTION, ĭn-vô-lŭ'shŭn, in mathematics, the raising by multiplication of a quantity to any assigned power. It is the inverse of evolution, in which the root of a quantity is extracted. See also ARITHMETIC—*Fundamental Operations* (Involution).

INVOLUTIONAL MELANCHOLIA, ĭn-vô-lŭ'shŭn-ăl mël-ăn-kô'li-ă, a psychotic condition which occurs during middle age. It is associated with the waning of physical vigor and generally appears between the ages of 40 and 60, being somewhat earlier for women than for men. The most common characteristic of involutional melancholia is mental depression, acute and intense. Self-recrimination, anxiety, fear, and attempts to commit suicide are features of the disease. Some patients exhibit symptoms of schizophrenia.

IO, ĭô, in Greek mythology, a priestess of Hera at Argos. According to most accounts she was the daughter of the river god Inachus. Zeus fell in love with her and, to protect her from the jealousy of Hera, changed her into a beautiful white heifer. Hera was not deceived, however, and sent a gadfly to torment Io, who was thus persecuted through many lands. Finally she reached Egypt, where Zeus restored her to her former condition and fathered her son Epaphus, ancestor of Danaus. Io has often been associated with Isis in Egypt. Her wanderings were a favorite subject in Greek poetry and painting.

In astronomy, Io is the traditional name applied to Jupiter's Satellite I, one of the four inner satellites discovered by Galileo in 1610, the first time any of the satellites of Jupiter was observed. See also JUPITER—*Satellites*; SOLAR SYSTEM.

IOANNINA, yô-ă'nyê-nă (formerly YANINA or JANINA, yă-nê-nă), city, Greece, in northern Epirus, capital of the Nome of Ioannina, situated on Lake Ioannina, approximately 200 miles northwest of Athens. The commercial center for an area producing grain, fruit, and wine, Ioannina has numerous silk and textile mills, and the gold and silver embroideries for which it was long famous are still manufactured. There is an airport. The city is the seat of a metropolitan of the Greek Orthodox Church and contains a number of early churches. There are many Byzantine ruins, including those of an ancient fort called the Iron Castle.

Ioannina was founded in Byzantine times. It was seized by the Normans in 1081, but soon reverted to imperial control and in 1204 became the capital of the despotate of Epirus, established by Michael Angelus Comnenus. Held by the Turks from 1431 to 1913, it was the residence of Ali Pasha, the Lion of Janina, from 1788 to 1822. Under Ali the city was very prosperous and became a prominent center of neo-Hellenic culture. After the First Balkan War, in 1913, it was annexed to Greece. It was heavily damaged during World War II. Pop. (1951) 32,315.

IODINE, ĭô-dĭn, the heaviest member of the halogen family of the chemical elements. The atomic weight is 126.91, and its atomic number is 53; its symbol is I. An isotope, I^{131} , occurs in the earth's crust, but no less than 18 radioactive isotopes of this element have been made, of which I^{131} is the most important.

Iodine is a solid at room temperature and melts at 113° C. Its boiling point is 184.35° C. The density of solid iodine is 4.94 at 20° C. In appearance it varies from a dense bluish black mass to lustrous crystals of the orthorhombic type. Iodine is slightly soluble in water, but is quite soluble in solutions containing inorganic iodides. It also dissolves readily in several organic liquids, including ethyl alcohol, diethyl ether, toluene, *p*-xylene, benzene, and carbon disulphide.

The discovery of iodine in 1811 or early 1812 is credited to Bernard Courtois, but the element was definitely isolated, described, and named by Joseph Louis Gay-Lussac in 1813. Its present name is derived from a Greek word (*iôdēs*) for the color of violets, because of the appearance of its vapor.

Iodine has seven electrons in its outermost orbit, and thus has a negative valence of one and positive valence of one to seven. Although not as active chemically as the other halogens, it forms compounds with most other elements except sulphur, selenium, and the zero-valence gases. It is a mild oxidizing agent and also a valuable catalyst.

Sources and Production.—Iodine is a relatively rare element in nature, but is present in sea water to the extent of 0.05 per cent. Brown seaweed has the ability to take up and concentrate this element until it contains, on the dry basis, as much as 0.45 per cent of iodine.

As early as 1840, iodine was discovered in the nitrate deposits of Chile, where it exists as an iodate. This is still the principal commercial source of iodine. Shortly after World War I, iodides were found in oil well brines in Louisiana and later in those of California. The latter furnishes most of the domestically produced iodine of the United States, but much greater quan-

tities are imported from Chile. The consumption of iodine in the United States is of the order of a million pounds per year.

Only a fraction of the iodine contained in the crude *caliche* from which sodium nitrate is produced in Chile is recovered each year, because of the limited quantities of iodine employed in the chemical industry. In fact, it is regarded as a fine chemical in contrast to heavy chemicals.

Iodine is obtained in Japan from the ashes of seaweeds by leaching the soluble sodium iodide, from which the free element is produced. Chilean nitrate iodine is liberated from the mother liquors of the nitrate industry by means of sulphurous acid, and the crude iodine is filtered, pressed, and sublimed from cement-lined retorts. American iodine from brines has been produced by a variety of processes, of which the simplest resembles that for the recovery of bromine from sea water, involving the blowing out of iodine by chlorine from an acid solution. The iodine is recovered from the vapors as hydriodic acid by scrubbing with sulphurous acid, and is converted to the element from concentrated solutions of the halogen acid by a second treatment with chlorine.

Derivatives.—The most common and important inorganic iodine derivative is hydrogen iodide (HI). It is a gas at ordinary temperatures, while its water solution is known as hydriodic acid. Potassium iodide (KI) is a commercial chemical and is the source of most of the iodides of other metals. Iodine also combines with other halogens, the two most common compounds being iodine monochloride (ICI) and iodine trichloride (ICl₃). Iodine pentoxide (I₂O₅) is a common chemical, of particular value because it oxidizes carbon monoxide to carbon dioxide, making possible the ready determination of the dangerous carbon monoxide substance. Iodic acid (HIO₃) and iodates (salts) are powerful oxidizing agents.

In the organic field, methyl iodide (CH₃I) is a standard methylating agent and fumigant, while methylene iodide (CH₂I₂) is a heavy liquid (specific gravity, 3.325) by means of which minerals may be separated. Iodoform is a medicinal disinfectant.

Uses.—Iodine and many of its compounds are of great value in chemical research. When iodine is used as an analytical reagent, the operation is known as *iodimetry*; when iodides are employed to determine the quantities of another substance that will liberate the iodine in them, the analysis is called *iodometry*. In either case, free iodine is determined by titration with sodium thiosulphate, the reaction being $3I_2 + 6Na_2S_2O_3 = 3Na_2S_4O_6 + 6NaI$. The indicator in thiosulphate titrations is a thin suspension of starch, which adsorbs free iodine to give a blue color. The indicator is not added until most of the iodine is converted to iodide to ensure a sensitive color change from blue to colorless. Many inorganic analyses depend on the use of iodine, and it also has many important applications in the field of organic analysis. Solutions of iodine or the monochloride bring about additions to double bonds of the glycerides of fatty acids, and by the use of rigidly standardized methods, animal and vegetable oils may be accurately identified. The term "iodine number" is the weight in grams of iodine that is taken up by 100 grams of an oil.

Iodine is of great importance in medicine, particularly in connection with the thyroid gland. The active thyroid hormone is a protein complex

containing the substance thyroxin (C₁₅H₁₁NO₄I₄). Radioactive iodine (I¹³¹) is employed in diagnosis and treatment of hyperthyroidism and thyroid cancer.

In the industrial field, although a fine chemical, iodine and its compounds find varied applications. Very pure titanium can be prepared by the formation of volatile titanium tetriodide, with decomposition and deposition on a vertical wire in the furnace. Silver iodide (AgI) is an ingredient of most photographic emulsions, being prepared from silver nitrate and potassium iodide and incorporated directly in the gelatin coating of films. It is also effective in very small quantities in the seeding of clouds to produce rain. Esters of hydriodic acid are organic reagents. Sodium iodide is added to table salt to prevent goiter. Several dyes contain iodine, such as rose bengale, iodine green, and erythrosin, the last being a certified food color and tissue stain. Numerous iodine preparations, of which iodoform and tincture of iodine are typical, are standard pharmaceuticals.

W. T. READ,
Chemical Consultant.

IODOFORM, i-ô'dô-fôrm, triiodomethane (CHI₃), an antiseptic once in very general use, but now largely displaced by more effective pharmaceuticals. It occurs as a yellow crystalline solid and melts at 119°C. Its density is about four times that of water. While only slightly soluble in water, it dissolves readily in benzene and acetone, is quite soluble in boiling alcohol, and very soluble in cold ether and carbon bisulphide. It was formerly employed in dressing wounds, but is somewhat irritating and may cause dermatitis. It still has some use in veterinary medicine, but when cows are treated with it, iodoform may appear in the milk.

Iodoform may be made from any organic compound containing a methyl group linked to a carbonyl group, as CH₃CO—, or a substance from which this group can be formed. The reaction is a quantitative test for such a group in organic analysis. Iodoform is made industrially by electrolyzing acetone or ethyl alcohol solutions of an inorganic iodide in the presence of sodium carbonate, or by the action of an alkaline solution of sodium hypochlorite on an iodide dissolved in alcohol or acetone. It also results from the interaction of chloroform (CHCl₃) and methyl iodide (CH₃I). Iodoform in alkaline solution oxidizes such compounds as arsenites to arsenates. Not more than five or six tons of iodoform are produced annually.

W. T. READ.

IOLA, i-ô'lâ, city, Kansas, seat of Allen County, situated on the Neosho River, 109 miles southwest of Kansas City, at an altitude of 960 feet. It is served by the Atchison, Topeka and Santa Fe, the Missouri-Kansas-Texas, and the Missouri Pacific railroads, and there is a municipal airport; the city is at the intersection of several U.S. highways. Iola is the commercial center for an important grain, livestock, and dairy farming district. Creameries and plants for condensing milk and processing food are in the city, and there are also factories for making bricks, cement, and clothing. Iola Junior College is located here, and the public library contains collections of state history materials and works by Kansans. Laid out in 1859, Iola became

a county seat in 1865 and was incorporated in 1870. It has a commission form of government. Pop. (1960) 6,885.

IOLANTHE, IOLANTA, or YOLANTA, opera in one act by Peter Ilich Tchaikovsky, with libretto by his brother Modest Ilich Tchaikovsky, based on the chivalresque play *King René's Daughter* by the Dane, Henrik Hertz. This, Tchaikovsky's last opera, was played for the first time at St. Petersburg on Dec. 17, 1892, on a double bill with the première of his ballet *The Nutcracker (Casse-Noisette)*. Although *Iolanthe* won temporary success in Slavic and Scandinavian countries, and has been revived there and in Central Europe in the mid-20th century, it seems never to have been given professional staging in England or the United States.

HERBERT WEINSTOCK.

IOLANTHE; OR THE PEER AND THE PERI, i-ô-lân'thê, pē'ri, operetta in two acts by Sir Arthur Sullivan, with libretto by William S. Gilbert. *Iolanthe* was first performed simultaneously at the Savoy Theatre, London, and the Standard Theater, New York City, on Nov. 25, 1882, running in London for 398 nights.

Act I.—Arcadian Fairyland. The Fairy Queen is persuaded to pardon the fairy Iolanthe, who for 25 years has been in exile as punishment for marrying a mortal. Iolanthe's son, the half-fairy, half-mortal Strephon, born after she left his father, wants to marry Phyllis, a shepherdess not yet of age; but Phyllis' guardian, the Lord Chancellor, has withheld his consent. The peers convene and try to persuade Phyllis to marry one of them, but she wants only Strephon. The lovers are separated. Mistakenly thinking Strephon unfaithful to her, Phyllis agrees to accept one of the peers. Strephon appeals to Iolanthe for help. She induces the Fairy Queen to arrange for Strephon to sit in the House of Peers, where he can upset all of his colleagues' political schemes.

Act II.—The Palace Yard, Westminster. After Private Willis, the sentry, sings a song, it becomes clear that the irresistible Strephon is creating havoc in the House of Peers. Phyllis has become engaged to both the Earl of Tolloller and the Earl of Mountarat, between whom she cannot choose. The Lord Chancellor decides to solve all problems by marrying Phyllis, whereupon Iolanthe, at the risk of her life, reveals that he is her husband, and, though he does not know it, the father of Strephon. Several other fairies reveal that they too have married peers and thus share Iolanthe's sin. The Fairy Queen relents and decides to marry Private Willis after changing all of the peers into fairies. Strephon and Phyllis are reunited, and all fly away happily to Fairyland.

HERBERT WEINSTOCK.

ION, i'ôn, in chemistry, an atom or group of atoms which has either lost or gained electrons, and has thereby acquired a positive or negative electrical charge. If the particle concerned has lost electrons, it is a positive ion or *cation*; if the particle has gained electrons, it is a negative ion or *anion*. Such ions may exist in pairs of opposite polarity as chemical units. When created by the dissociation of a chemical compound, the ion may occur variously as an electrically charged atom, molecule, or radical.

A stable solid, liquid, or gaseous compound is also in an electrically neutral state, the positive charge of the metallic ion it contains being electrically balanced by the negative charge (or charges) of its constituent nonmetallic ion. However, if a *polar* dissociating compound is placed in water, a certain number of the metallic ions of the compound separate from their chemical bond with the nonmetallic ion or ions of the compound to destroy the former electrical balance. The charged particles thus released become free ions in the solution. These ions are capable of chemical recombination (ion exchange) to fill the valence electron shells of other atoms and thus form new compounds.

Typically, when a substance such as hydrochloric acid is mixed with water, a process of dissociation occurs as part of the acid separates into charged H^+ and Cl^- ions. If a weak electric current is passed through the solution by means of two metal bars known as electrodes immersed at different points in the solution, a process of ion migration takes place. With the current turned on, as electrons leave the one electrode (anode) to flow into the solution, this electrode with a deficiency of electrons becomes positively charged. Similarly, because of the accumulation of electrons leaving the solution, the opposite electrode (cathode) becomes negatively charged. The positively charged hydrogen ions in the solution thus tend to flow toward the negatively charged cathode, where each seizes an electron to form a neutral, electrically stable hydrogen atom. The negative chlorine ions in solution migrate toward the positively charged anode, where they yield their free electrons to become stable chlorine atoms. (See also ELECTROLYSIS.)

In this capacity of making possible a continuous flow and interchange of electrons between two electrodes and thus permitting conduction of an electric current through a solution, ions also form the basis of a wet storage battery (see BATTERY, ELECTRIC). So-called *nonpolar* (including most organic) compounds formed by sharing electrons in a covalent bond, do not create ions and are therefore nonelectrolytic. They will not conduct an electric current.

In geophysics, the ion represents a charged particle formed from molecules or atoms of atmospheric gas by the ionizing action of ultraviolet rays and X-rays (or by the impact of α particles) from the sun, at high altitudes where the absorbing effect of the earth's atmosphere for these short-wave radiations and corpuscular streams is not as great as at lower levels. Several layers of free ions are formed by these processes in a high-level region of the atmosphere called the *ionosphere*. (See also IONOSPHERICS.)

In physics, ions are the basis for many phenomena of electric discharge tubes, and permit the flow of electric current in evacuated fluorescent and neon light tubes and other such devices.

IONA, i-ô'nà, island, Scotland, one of the Inner Hebrides, in Argyllshire, about one mile west of the Ross of Mull, from which it is separated by Iona Sound. The island is approximately three miles long and one and one-half miles wide, with a total area of three and one-half square miles. About one third of the land is under cultivation, chiefly to oats, barley, and potatoes. The remaining area consists of hilly

pasture (suitable for grazing), rocky hills, and shell beaches. There is marble quarrying, and fishing and tourism are additional sources of income. The island has no trees.

About 563, St. Columba (q.v.) and his companions came from Ireland and founded the monastery which soon made Iona the most famous center of Celtic Christianity. Missionaries from Iona went to all parts of Scotland and northern England, establishing monasteries and spreading Christianity, while to Iona came students and pilgrims, many of the latter coming to die and be buried in the holy soil. During the 8th and 9th centuries the island was raided many times by Vikings, and the monastery was burned. It was restored in the 11th century by Queen Margaret, wife of Malcolm III MacDuncan of Scotland; she is also said to have built St. Oran's Chapel, the oldest existing building on the island (c. 1080). A new monastery was established in 1203 by the Benedictines, but with the success of the Reformation in Scotland, it was dismantled (1561). The Cathedral of St. Mary has 13th century remains, but dates mainly from the 15th and early 16th centuries, with much subsequent restoration. Also of interest is St. Oran's Cemetery, containing some of the sculptured tombstones of the many early kings and chiefs of Scotland, Ireland, and Norway who were buried on Iona. There are remnants of the numerous crosses which once covered the island, and still standing is the 14-foot Iona Cross, of carved granite, dating possibly from the 9th or 10th century. The Iona Community, a brotherhood of ministers and laymen, has undertaken the restoration of the monastery and other buildings on the island.

IONESCU, yō-ně'skōō, **Take**, Rumanian statesman: b. Ploesti, Rumania, Oct. 13, 1858; d. Rome, Italy, June 21, 1922. Educated in law at Bucharest and Paris, he entered Parliament in 1884, held various ministerial posts, and in 1908 founded the Conservative Democratic Party. At the end of the Second Balkan War (1913) he represented Rumania at the Bucharest Peace Conference, securing the remainder of Dobruja from Bulgaria. Ionescu was a leading advocate of Rumania's participation in World War I on the side of the Allies. After his country entered the war (1916), its armies were crushed by Germany and Austria, but it acquired Bucovina, Transylvania, and Bessarabia at the end of the conflict, thanks in great part to Ionescu's efforts at the Paris Peace Conference. As foreign minister (1920-1921) under Gen. Alexandru Averescu, he negotiated the treaties with Czechoslovakia and Yugoslavia (1921) which formed the basis of the Little Entente, designed to defend the peace treaty awards. He succeeded Averescu as prime minister briefly in 1921-1922.

IONIA, i-ō'nī-ā, ancient district, Asia Minor, covering a narrow strip of land in western Anatolia (Turkey), along the Aegean Sea, and including the islands of Samos and Chios, as well as many other Aegean islands. The mainland area extended about 90 miles, from the mouth of the Hermus (modern Gediz) River to the Halicarnassus (modern Bodrum) Peninsula, going inland about 20 to 30 miles, where it was bordered on the east by the Lydian kingdom. According to tradition the region was settled about 1000, B.C. by Greeks from Attica, who were fleeing the in-

vading Dorian barbarians. Ionia contained the most fertile soil in Asia Minor and, located between the Greek mainland and the Asian hinterland, was well situated for trade. The region prospered and 12 wealthy cities arose: (north to south) Phocaea, Clazomenae, Erythrae, Teos, Lebedos, Colophon, Ephesus, Priene, Myus, Miletus, and the island cities of Chios and Samos. The 12 city states—with the later addition of Smyrna—formed a loose religious league, although they retained their individual political autonomy.

A brilliant culture flourished very early in the Ionian cities, and this was widely disseminated by the energetic Ionians, who traveled about the ancient world to trade and establish daughter colonies along the shores of the western Mediterranean and the Black Sea. The Ionian schools of philosophy, art, poetry, and literature were of great significance in the later development of Athenian culture.

In the 7th century B.C., Ionia was invaded by the Cimmerians, and later by the Lydians. The cities were finally subjected by King Croesus (r. 560-546 B.C.) of Lydia, and about 547 B.C. they fell to Cyrus the Great of Persia. In the struggle to regain their freedom the cities became involved in the wars of Persia and Greece and finally fell to Alexander III the Great (r. 336-323 B.C.) of Macedon. Under the domination of Rome and Byzantium they remained culturally significant, but with their conquest by the Turks in the 11th century they fell into decline.

IONIA, city, Michigan, seat of Ionia County, situated on the Grand River, 33 miles east of Grand Rapids, at an altitude of 650 feet. It is served by the Grand Trunk and the Chesapeake and Ohio railroads, a county airport, and state and federal highways. Ionia is the trading center for an area growing wheat, apples, and livestock; the city has flour mills and meat-packing plants, and among the varied goods produced by its factories are reed furniture, pottery, machinery, edged tools, automobile bodies, tile, and clothing. The Michigan State Reformatory and the Ionia State Hospital for the criminally insane are located here.

Settled in 1833, Ionia was incorporated as a village in 1865 and as a city in 1873. Its charter was revised in 1897 and 1924, and the city is governed by a mayor and council. Pop. 6,754.

IONIAN ISLANDS, i-ō'nī-ān, island group, Greece, in the Ionian Sea, off the southwest coast of Albania, west and south of the Greek mainland and the Peloponnesus. From north to south the seven principal islands are: Corfu (Kérkyra); Paxos (Paxoi), including Antipaxos; Leukas (Lévkás); Cephalonia (Kephallénia); Ithaca (Ithákē); Zante (Zakynthos); and Kýthēra (Cérigo), including Antikýthēra. Kýthēra and its dependency are under the Nome of Attica; the remaining islands are divided into the four nomes of Corfu, Leukas, Cephalonia, and Zante, with a total area of 751 square miles. Although each island has its individual character, all are mountainous and lack sufficient arable land to produce the grain required to support the population. The climate is mild, and rainfall, especially high in Corfu, averages about 50 inches a year. The principal crops are olives, grapes, and currants; these, together with wine and olive oil, are shipped to the mainland and to foreign countries.

Some livestock is raised, and there is local fishing. Industry is generally undeveloped.

The islands often figured individually in the history of ancient and medieval Greece. They became part of the Byzantine Empire in 330 A.D., when the capital of the Roman Empire was moved to Byzantium (Constantinople). Corfu was captured by the Norman adventurer Robert Guiscard in 1081, retaken by Manuel I Comnenus in 1149, and acquired by Venice in 1386; from the 15th century on, the other islands also became Venetian dependencies. In 1797, under the Treaty of Campoformio, they were ceded to France, but were taken by Russia in 1798-1799. From 1800 to 1807 they formed the Septinsular Republic under Ottoman sovereignty and Russian protection.

After an eight-year period of renewed French rule, the islands became a British protectorate under the Treaty of Paris (Nov. 9, 1815), and were called the United States of the Ionian Islands. Governed by a British high commissioner, they were granted a constitution (1817), which provided for a senate and a legislative assembly whose decisions were subject to the commissioner's veto. Until 1864, when Greece took over the islands, nine high commissioners ruled the protectorate. During this period the island developed politically and socially: public works were constructed, trade was encouraged, and the first Greek university was set up when Frederick North, 5th earl of Guilford, founded the Ionian Academy in 1824. A school of modern Greek poets flourished, with Dionysios Solomos (1798-1857) and Aristotelis Valaoritis (1824-1879) as its outstanding representatives.

The emergence of an independent Greece in 1830 created tension between the Greeks in the islands and the British authorities, and the French revolution of 1848 sparked riots in Cephalonia and a call for union with Greece. The following year constitutional reforms were introduced, including direct election of representatives to the legislature, but the struggle for union continued. Finally, during the search for a successor to King Otto I, who had been ousted from the Greek throne in 1862, the British government decided to cede the islands to Greece. The treaty of July 13, 1863, providing for the accession of George I to the Greek throne, included a provision for the union of the islands to the motherland. On August 1, Austria, Russia, and France consented to this revision of the treaty of 1815, and on October 5 the newly elected Ionian Assembly voted for union with but three dissenting voices. By a three-power treaty of Nov. 14, 1863, the islands were neutralized in perpetuity, and on June 2, 1864, Greece took possession. See also separate articles on individual islands. Pop. (1951) including K  th  ra, 236,119.

STEPHEN G. XYDIS,
Columbia University.

IONIAN SCHOOL OF PHILOSOPHY, the earliest group of Greek philosophers, antedating Socrates and hailing from the Ionian cities of Asia Minor. Thales, Anaximander, and Anaximenes, all of Miletus, and Heraclitus of Ephesus, were important early members of the group; Pythagoras, Anaxagoras, and Leucippus also came from Ionia. See also articles on the individual philosophers; **PHILOSOPHY**, **HISTORY OF**.

IONIAN SEA, a northern extension of the Mediterranean Sea, lying between the west coast

of Greece on the east and the southeast coast of Italy and the east coast of Sicily on the west. It connects with the Adriatic Sea by the Strait of Otranto and with the Tyrrhenian Sea by the Strait of Messina. To the northwest it forms the gulfs of Squillace and Taranto, and in its eastern waters off the coast of Greece are the Ionian Islands. Its chief ports include Syracuse in Sicily, Corfu and Patras in Greece, and Taranto in Italy.

IONIC ORDER, i-  n'  k, in architecture, the second of the three Greek orders (see **ORDERS OF ARCHITECTURE**), probably taking its name from the district of Ionia in Asia Minor. It may have sources in Phoenician (the lotus motif) or Assyrian (the honeysuckle) styles, but the question is unimportant, since its chief significance is as a Greek form of expression.

The Ionic column is characteristically 9 diameters high (as against 8 for the Doric and 10 for the Corinthian). The most important feature is the capital, which is rectangular and ends in large double scrolls or volutes (usually carved from separate blocks), with a palmette springing from the return of the volute upon itself, like a leaf or husk. The base is often a plinth carrying two rounded protruding forms separated by a hollow molding. In the entablature, the architrave is decorated with two or three bands, each wider and further out than the one beneath; the frieze is plain, and the cornice is distinguished by a dentil band, all as opposed to the Doric order (q.v.).

The flutings of Ionic columns may vary from none to 14, 18, 20, or, according to the Roman architect Marcus Vitruvius Pollio, 24 in number, and are generally semicircular in shape, although the flutings at the Propylaea and the Erechtheum in Athens are elliptical.

The history of the Ionic order in the ancient world shows a development from a flaring to a more refined ideal among the classical Greeks; then, with the Hellenistic period, comes a larger, more imposing scale. These tendencies were further pursued by the Romans, at whose hands the volutes became smaller and the details generally coarser and heavier, as is usual with Roman adaptations of Greek forms.

Among Greek styles, the Ionic stands between the Doric and the Corinthian. The Doric is a pure expression of structural power, bearing overtones—though never representations—of the human figure, with trunk (shaft) and head (capital), all abstract, compact, and swelling with a muscular sense of weight and counterthrust. The Ionic, being more attenuated, dissipates this force, and the capital with its volutes suggestive of horns (as on a ram), scrolls, or leaves (as in vegetation) carries a swinging ornamental effect, though still embodying a feeling of curling with the weight of the architrave. The Corinthian order (q.v.) in turn becomes more attenuated and its capital more decoratively suggestive of foliage, thus more pictorial and less architectural.

The intercolumniation, which in the Doric remained compact and strictly measured to the diameter of the column, in the Ionic and Corinthian becomes wider and loses its positive shape, leaving the columns alone in vapid space. In the later orders the details, addenda, and execution become far more articulated and refined, but the strong feeling of structural symbolism is largely lost.

The Ionic is a self-conscious style, standing on its own elaborated pedestal, as opposed to the Doric, which like the Gothic style in western European development seems naturally to grow out of the ground. In this sense Ionic may be compared with Renaissance-baroque architecture. Yet, just as the Gothic and baroque styles could be successfully combined (as in the Church of St. Lorenz at Nürnberg, Germany) because of the continuity of their formal character, so Doric and Ionic were not infrequently combined in the same building, as in the Propylaea, a Doric building with Ionic inner columns.

Outstanding examples of the Ionic order were the Erechtheum and the temples of Athena Polias and Athena Nike in Athens, the Temple of Apollo at Bassae (Phigalia), the rebuilt temple at Ephesus, and the Temple of Fortuna Virilis in Rome. See also COLUMN.

Columbia University.

IONOSPHERICS, ĭ-ŏn-ô-sfēr'ĭks, the scientific study of the electrically charged region of the earth's atmosphere which lies above the stratosphere (and chemosphere) and because of its composition of free electrons and positive ions is known as the *ionosphere*. The lower boundary of this atmospheric region is at an altitude of approximately 50 miles. The upper boundary has been set by various investigators at 250 to 500 miles or higher, and merges into the exosphere. (See ATMOSPHERE—*Divisions of the Atmosphere*.)

Within the ionosphere, the minute electrically charged particles known as ions are concentrated in belts or layers, and are created principally by the ionizing effects of streams of ultraviolet radiation and X-rays from the sun. The presence of the sun in the sky is a governing factor affecting both the degree of ionization and electron density of the several ionic layers. These quantities may, accordingly, vary with the time of day, the latitude, and season of the year.

The so-called *D ionic region*, which occurs just below 50 miles during the day, forms the base of the ionosphere. The superadjacent layer, called the *E ionic layer* or Kennelly-Heaviside layer, lies during daylight hours between approximately 60 and 80 miles. A transient or *sporadic E layer* also exists occasionally at about 70 miles, and is independent of solar influences. The next higher stratum, the *F ionic layer* (often called the Appleton layer after its discoverer, Edward V. Appleton) is found at night at an altitude of approximately 150 miles. During the daylight hours, it splits into two layers. The lower of these is termed the *F₁ ionic layer* and occupies a belt between approximately 110 and 140 miles; the other, the *F₂ ionic layer*, normally exists between 180 and 200 miles. The *G ionic layer* is found less frequently at heights above 400 miles and only in the vicinity of the equator.

The various ionic layers act in a fashion similar to layers of unequal optical density in refracting (see REFRACTION) radio waves which pass through them. Radio sky waves are bent and recurved until eventually they are directed back toward the earth's surface again. Broadcast-frequency radio waves (500–1500 kilocycles per second) are refracted back by the lower E layer. High-frequency or short-wave radio signals (3–30 megacycles per second) penetrate to the higher

F₁ or F₂ layers before being recurved earthward, and their energy is not as fully absorbed. With the lifting of the ionic layers at night, distance reception also usually improves.

The ionosphere is markedly influenced by electric storms in the earth's high atmosphere caused by pronounced sunspot activity, solar flares, and chromospheric eruptions on the sun, which when active may severely disrupt short-wave radio communication, telegraph, telephone, and cablegraph service. Systematic governmental radio-propagation surveys are now maintained to forecast ionospheric storms and avoid such signal disruptions.

FERGUS J. WOOD,
United States Coast and Geodetic Survey.

IORGA, yŏr'gă, Nicolae, Rumanian statesman and scholar; b. Botoșani, Moldavia, Rumania, June 17, 1871; d. near Bucharest, Nov. 28, 1940. As a young student in Iași, he became interested in the development of a Rumanian national literature with the folk traditions of the Rumanian peasant as its inspiration. After studying in France and Germany (1890–1894), he returned to Rumania and became professor of world history at the University of Bucharest. In this post and as editor (1903–1906) of the periodical *Samănătorul* (*The Sower*), Iorga exerted great influence in fostering the growth of a native spirit in Rumanian literature. During these years he also brought out five volumes (1901–1909) of Rumanian literary history, which he brought up to date in 1934 with two volumes on modern literature.

Iorga's political career began in 1906 when he helped found the National Democratic Party, and in 1907 he became a deputy in the Rumanian Parliament, in which he served continuously from 1918 until his death. After World War I he was president of the national assembly which achieved the union of Bucovina, Transylvania, and Bessarabia with Rumania. From 1931 to 1932 he was minister of education and prime minister of the coalition government established by King Carol II. He was assassinated by troops of the Iron Guard shortly after the Germans occupied the country in World War II.

The list of Iorga's writings contains nearly 2,000 titles, including plays, stories, translations, and editions of historical documents. His major writing, in the field of history, includes such works as *Geschichte des rumänischen Volkes* . . . (2 vols., 1905); *Geschichte des osmanischen Reiches* (5 vols., 1908–13); *Notes et extraits pour servir à l'histoire des croisades* . . . (6 vols., 1899–1916); and *Essai de synthèse de l'histoire de l'humanité* (4 vols., 1926–28). He also published *My American Lectures* (1932).

IOS, ĭŏs, Gr. ēŏs, or **NIO**, nyē'ô, island, Greece, in the Cyclades group in the Aegean Sea, approximately 13 miles southwest of the island of Naxos. It is about 12 miles long and five miles wide, with a total area of about 45 miles. The principal occupations are the cultivation of cotton, barley, and olives. Olive oil and wine are produced. Ios is one of the many places mentioned in legend as the birthplace (and burial place) of Homer.

IOSHKAR-OLA, yôsh-kâr' ŭ-lá', city, USSR, capital of the Mari Autonomous Soviet Socialist Republic, a division of the Russian Soviet Federated Socialist Republic. Ioshkar-Ola is situated on the Malaya (Little) Kokshaga River, a left tributary of the Volga, and 75 miles northwest of Kazan, with which it is linked by a railroad. Ioshkar-Ola is situated at the boundary between the northern timber area of the Mari Republic and the agricultural south, and thus combines wood and farm-processing industries. The city also has developed manufacturing industries, producing electrical instruments, movie projectors, weighing scales and vitamins. Ioshkar-Ola is the focus of roads serving the Mari Republic. The city has timber-engineering and teachers' colleges and is the seat for Mari cultural institutions. Founded in 1584, the town was known as Tsarevokokshaik in czarist times. Under the Soviet regime, its population increased rapidly, rising from 4,374 in 1926 to 89,000 in 1959.

I.O.U., in law, is an informal acknowledgment of indebtedness. It is distinguishable from a promissory note, which consists of an express promise to pay a definite sum of money, by containing merely an implied promise to pay. By the weight of judicial authority, an I.O.U. is enforceable in the courts. The legislatures of some states have similarly extended the law of bills and notes to include any written instrument whereby any person acknowledges a sum of money to be due to another person. An I.O.U. has been defined as a written memorandum of debt, consisting of these three letters, a statement of the amount, and the debtor's signature. Even though an I.O.U. may be adequate, with respect to form, to constitute a valid acknowledgment of debt, recovery in court may be denied in particular cases for reasons relating to the nature of the underlying transaction. For example, an I.O.U. given for a gambling debt might be unenforceable for reasons of public policy. Also, of course, the instrument must be based on a legally sufficient consideration in order to constitute a valid promise to pay.

RICHARD L. HIRSHBERG.

IOWA, í'ô-wà, a Middlewestern state of the United States, situated between the Mississippi River on the east and the Missouri and Big Sioux rivers on the west. The state is bounded by Minnesota on the north, by Wisconsin and Illinois on the east, by Missouri on the south, and by

State flag

Nebraska and South Dakota on the west. It is roughly 300 miles from the east to the west boundary, and 200 miles from north to south.

The meaning of the Indian word *Iowa* is not definitely known, although several possible translations, including "beautiful land," "this is the place," and "one who puts to sleep," have been offered.

Total area	56,290 square miles
Land area	56,045 square miles
Water area	245 square miles
Latitude	40° 24' to 43° 30' N.
Longitude	90° 5' to 96° 40' W.
Altitude (average)	1,100 feet
High point, Ocheyedan Mound	1,675 feet
Low point, Mississippi River	480 feet
Population, 1960	2,757,537
Capital—Des Moines; population	208,982
Admitted to Union as 29th state	Dec. 28, 1846
State motto	<i>Our Liberties We Prize and Our Rights We Will Maintain</i>
(adopted Feb. 25, 1847)	
State bird (adopted March 22, 1933)	Eastern goldfinch
State flower (adopted May 7, 1897)	Wild rose
State tree (adopted 1961)	Oak
State song (adopted March 20, 1911)	<i>Iowa</i>
State nickname	Hawkeye State

State seal

Iowa has long been one of the leading agricultural states in the nation. Early settlers found the soil and climate favorable for bountiful harvests of food and feed grains. Wise farming practices and the acceptance of modern agricultural technology, including mechanization, have resulted in increased production and an exceptionally high standard of living for farmers, but have also brought about a numerical decrease in the agricultural population, part of the surplus of which has found employment in manufacturing plants. Since 1950, the value of manufactured goods has come to rival and even exceed that of raw agricultural produce, although the state still contributes about one tenth of the national food supply. During the two decades after 1940, more persons moved out of Iowa than moved into it, but the total population continued to rise because of natural increase.

A discussion of Iowa's geography, government, social and economic life, and history is presented under the following headings:

1. Physical Features
2. Population and Political Divisions
3. Government
4. Education, Health, and Welfare
5. Economic Activities
6. Transportation and Communications
7. Cultural Life
8. Places of Interest
9. Famous Men and Women
10. History
11. Bibliography

1. PHYSICAL FEATURES

Most of the surface of Iowa is a glacial plain that slopes from the northwest to the southeast, from Ocheyedan Mound in Osceola County, the highest point (1,675 feet), to the mouth of the Des Moines River in Lee County (480 feet). Approximately two thirds of the state is between 800 and 1,400 feet above sea level.

Topography.—The watershed runs from the northwest part of the state to the southeast. About two thirds of the total area drains into the Mississippi River by way of the Upper Iowa, Turkey, Wapsipinicon, Cedar, Iowa, Skunk, Racoon, and Des Moines rivers. The western part of the state drains into the Missouri River through such streams as the Rock, Little Sioux, Boyer, and Nishnabotna. The south central part of Iowa is drained by the Nodaway, Thompson, and Chariton rivers through northern Missouri and into the Missouri River.

Glacial drift formed a number of small lakes in the northwest. Lake Okoboji, Spirit Lake, and Clear Lake are the largest of the 13 natural lakes in Iowa. There are also several artificial lakes, supervised by the State Conservation Commission.

Climate.—Iowa's climate is the humid, continental, long-summer type. In winter, cold air masses from northwestern Canada sweep across the state, bringing below-zero temperatures; summer temperatures are high, showing the effect of continentality. Average January temperature at Des Moines, which is centrally located in the

The oldest outcrop of rock, Proterozoic, is found in the northwestern corner of the state. In northeast Iowa, Cambrian and Ordovician rocks outcrop in high bluffs along the Mississippi River. Because of the rugged topography and the presence of a dairy economy, this section has been called the "Little Switzerland" of Iowa.

Evidence of five different glaciers can be found in Iowa. The deposits left by each glacier range from 10 to 150 feet in depth; this glacial deposit was the parent material for soil formation. A correlation between the economic life of the state and this prehistoric influence can be illustrated with almost mathematical exactness by superimposing a 20th century resources map on a glacial map of the state. The last invasion of glacial ice (the Wisconsin, estimated to have occurred about 10,000 to 12,000 years ago) covered about 20 per cent of the state and was especially beneficial to what are now the north central counties. In this area the soil is especially rich and the land is relatively level and poorly drained.

state, is 22.8° F.; the July average is 77.1° F.

Frequent cyclonic storms are associated with winter precipitation, usually in the form of snow, which averages about 30 inches per year. The summer maximum precipitation is mainly from convectonal thundershowers which permit a high percentage of sunshine during the growing season. Annual rainfall is also around 30 inches a year and is dependable; seldom is precipitation so low that crop failure occurs. The growing season lasts from early May to the first part of October. Northwest Iowa usually has 140 frost-free days a year, southern Iowa nearly 170 days frost-free. The average length of the growing season is 156 days. Hailstorms and tornadoes, the latter occurring usually in May and June, are the most destructive types of summer storms. Infrequent blizzards in winter are less destructive now than in the past, since their arrival is predicted.

Native Vegetation.—Two types of native vegetation existed in Iowa before the white man arrived. The oak-hickory forest, together with

some ash, black walnut, elm, and box elder grew along most of the streams and covered about one fifth of the present state. Prairie grassland was found between the rivers, covering a much larger percentage of the land. Tall, luxuriant, and relatively deep-rooted grasses, principally bluestem, bunch grass, and Indian grass, were mixed with a large variety of herbaceous flowering plants. In the early spring, phloxes, shooting stars, and spiderworts added variety and color to the landscape. The original prairie grassland can now be seen in only a few places. Three prairie grass preserves are supervised by the State Conservation Commission.

Animal Life.—The early settlers found the Iowa prairie and forests full of game and the rivers well stocked with fish. Muskrat, raccoon, skunk, rabbit, and gopher are still common. The white-tailed or Virginia deer is increasing, and there is a short deer-hunting season each year. Poultry raisers still find the red fox a predator. Small birds that either live in or migrate through the state by means of the Mississippi-Missouri flyways include the cedar waxwing, cardinal, junco, thrush, sparrow, starling, Eastern goldfinch, chickadee, blackbird, robin, and woodpecker. The ring-necked pheasant was imported and is now a major game bird. Prairie chicken, wild turkey, and wild pigeon have disappeared. Hawks and owls are the chief predatory birds.

A variety of fish in the rivers and lakes offer limited commercial possibilities, as well as recreation for sportsmen. Among the common types are catfish, bullhead, carp, walleyed pike, bluegill, perch, smallmouthed bass, and trout.

Conservation.—Iowa's most valuable natural resource is soil, and considerable attention is given to conservation practices. About 46 per cent of the state is classified as "soil erosion unimportant," but in another 45 per cent sheet erosion is moderate with considerable gullying locally, and in the remaining 9 per cent of the state there is severe sheet erosion with moderate to severe gullying. Numerous conservation practices are utilized, such as terracing, contour farming (about 35 per cent of the cropland is contoured), permanent sod waterways (more common than in any other state of the nation), drainage (in the north central section of the state), and dams, built principally for erosion control.

Water conservation has received much attention in recent years because of increasing demands for this resource by industry, municipalities, and agriculture. Annual runoff is estimated to be about 20 per cent of the yearly precipitation. Iowa is in the process of establishing a definite water policy, and the State Natural Resources Board has conducted watershed studies and programs for the larger and some of the smaller streams. Thousands of farm ponds or tanks have been constructed, most of which are in southern Iowa, where some cities depended partially or entirely on artificial reservoirs for their water supplies.

2. POPULATION AND POLITICAL DIVISIONS

Population Characteristics.—Early settlers of Iowa came from the eastern and southern areas of the United States. Immigrants from northern Europe were attracted to available Iowa farms in the mid- and late 19th century. German, Scandinavian, and Irish communities were especially evident; Dutch, Bohemian, French, and

other national groups came in smaller numbers. Some communities continue to have bilingual residents although, by 1960, less than 1.5 per cent of the state's white population was foreign born. Some Negroes migrated north to Iowa during the Civil War, and 20th century industrial development attracted Negroes to the larger cities. In 1950 the Iowa population of 2,621,073 represented an increase of 3.3 per cent over the 1940 census figure, and the 1960 total of 2,757,537 was up 5.2 per cent from 1950, but these gains were far below the national average. Density of population averaged 49.2 per square mile in 1960, and 47 per cent of the state's citizens resided in areas classified as rural.

Political Divisions.—Local government areas created by state authority comprise counties, townships, school districts, and towns and cities.

Cities and Towns.—A town may be incorporated when at least 25 voters favor the action. In the 1960 census, there were 20 cities having a population of at least 15,000, and 108 with populations between 2,000 and 15,000. Towns are classified as those communities with populations under 2,000; there were over 800 such incorporated places. Davenport, Muscatine, Wapello, and Comanche have special charters granted before the adoption of the constitution of 1857. Cities of more than 15,000 population in 1960 were:

Des Moines	208,982	Burlington	32,430
Cedar Rapids	92,035	Mason City	30,642
Sioux City	89,159	Fort Dodge	28,399
Davenport	88,981	Ames	27,003
Waterloo	71,755	Marshalltown	22,521
Dubuque	56,606	Cedar Falls	21,195
Council Bluffs	54,361	Muscatine	20,997
Ottumwa	33,871	Keokuk	16,316
Clinton	33,589	Newton	15,381
Iowa City	33,443	Fort Madison	15,247

Townships.—Townships continue to be geographical and political units in Iowa, but they have diminishing powers. Township trustees and clerks are elected, and some townships continue to elect constables and justices of the peace.

School Districts.—School districts receive their powers from the Iowa General Assembly. District reorganization was accelerated in the 1950's by a requirement that all land must be in a district that operates a four-year high school.

Counties.—There are 99 counties in Iowa, ranging in population from Polk with 266,315 in 1960 to Adams with 7,468. Kossuth is the largest, with an area of 979 square miles, and Dickinson the smallest, with 382 square miles. Voters elect the following county officers: supervisors, sheriff, attorney, coroner, auditor, recorder, clerk of court, and treasurer. A list of the counties and their county seats follows:

COUNTY	COUNTY SEAT	COUNTY	COUNTY SEAT
Adair	Greenfield	Clarke	Osceola
Adams	Corning	Clay	Spencer
Allamakee	Waukon	Clayton	Elkader
Appanoose	Centerville	Clinton	Clinton

Monroe	Onawa	Wright	Clarion			
Montgomery	Red Oak					

3. GOVERNMENT

State Constitution.—Iowa became a state in 1846, and its first constitution remained in effect until the adoption of the present constitution in 1857. Twenty-one amendments had been added to the latter by 1964. A majority vote of two successive legislatures and a majority vote of the people is required to amend the constitution. The General Assembly is also instructed in the constitution to submit, after each federal census, the following question to qualified voters: "Shall there be a convention to revise the constitution, and amend the same?" A bill of rights is provided for, as well as the basic structure of government and a definition of its powers and limitations. Voters are required to be United States citizens at least 21 years old, and to have resided in Iowa for at least six months and in the county for at least 60 days.

Iowa has 7 members in the U.S. House of Representatives and 2 United States Senators.

Executive.—The governor, lieutenant governor, secretary of state, attorney general, treasurer, auditor, and secretary of agriculture are elected for two-year terms. These officials, with the exception of the lieutenant governor and the attorney general, form the state Executive Council. The governor is aided by an administrative assistant and the state comptroller. There are numerous commissions, boards, and agencies to supervise public schools, institutions of higher learning, health, social welfare, penal and mental health institutions, public safety, highways, aeronautics, industry, banking, insurance, labor, and personnel.

The state capitol at Des Moines.

representative, and the nine most populous counties elect two. There are 50 senators, each elected for four years. The constitution calls for Senate redistricting after each federal census, but this was not done for 50 years and by 1960 district populations varied from 20,000 to 200,000. An amendment reapportioning the legislature received a first Assembly passage in 1961, and a second Assembly passage in 1963. It would create 58 Senate districts, based on population, and 99 House districts, one for each county.

Judiciary.—The Iowa Supreme Court is composed of nine justices, who are elected for six-year terms. Iowa counties are organized into 21

district courts, which have extensive jurisdiction over civil and criminal cases. The 71 District Court judges serve four-year terms. A constitutional amendment making Supreme Court and District Court judgeships appointive instead of elective won final approval by the electorate in the 1962 primary. Cities and towns have superior or municipal courts, and some townships still elect justices of the peace for two-year terms.

Taxation.—The Iowa budget is prepared by the comptroller with the approval of the governor and is adopted or modified by action of the state legislature. The State Tax Commission administers taxes on beer, chain stores, cigarettes, inheritances, insurance companies, corporation income, individual income, and sales and use taxes. The State Safety Department collects fees relating to the use of automobiles. The state treasurer collects gasoline taxes. Since 1933, property tax has been used principally to support local areas of government. The largest annual income is derived from the sales, gasoline, and individual income taxes.

4. EDUCATION, HEALTH, AND WELFARE

Public Schools.—At mid-century, Iowa led the nation in its small percentage of illiterate residents (0.8 per cent). It has also been conspicuous as a state of numerous and small school districts. In the pioneer communities, schools were financed by rates paid by the patrons; preparatory academies were operated by churches or local communities. Public schools are now supported by

duced from 4,417 in 1954-1955 to 1,231 in 1962-1963. Voters in the community school district elect a board that employs the superintendent and teaching staff. The state superintendent of public instruction is employed by a nine-member State Board of Instruction. The state office administers state aid funds to local schools, certifies teachers, and supervises school bus transportation, help for exceptional children, vocational education, veteran training programs, the school lunch program, and all tax-supported junior colleges. The intermediate school authority on the county level enforces state law locally and gives various types of help to the local schools. Few courses are required by state law, and the local school plans much of its own program.

Higher Education.—Iowa has three institutions of higher education under the supervision of the Board of Regents: the State University of Iowa at Iowa City (founded in 1847), the Iowa State University of Science and Technology at Ames (1858), and the State College of Iowa at Cedar Falls (1876, known before 1961 as Iowa State Teachers College). The nine members of the Board of Regents are appointed for staggered six-year terms by the governor, with the consent of the Senate. A number of public junior colleges are included in the local public school system.

From territorial days, Iowa has had a strong tradition of church-supported liberal arts colleges. Those currently operating include Briar Cliff College at Sioux City, Buena Vista College at Storm Lake, Central College at Pella, Clarke College at Dubuque, Coe College at Cedar Rapids, Cornell College at Mount Vernon, Drake University at Des Moines, University of Dubuque at Dubuque, Graceland College at Lamoni, Grinnell College at Grinnell, Iowa Wesleyan College at Mount Pleasant, Loras College at Dubuque, Luther College at Decorah, Marycrest College at Davenport, Morningside College at Sioux City, Parsons College at Fairfield, St. Ambrose College at Davenport, Simpson College at Indianola, Upper Iowa University at Fayette, Wartburg College at Waverly, Westmar College at Le Mars, and William Penn College at Oskaloosa.

Libraries.—The state maintains a traveling library at Des Moines to help small libraries and to serve localities having no public libraries. Free public libraries are supported by local taxation. Public schools are expected to have at least a part-time librarian to care for the school book collection.

There are four libraries in the state where research may be profitably pursued. The library of the State University of Iowa, at Iowa City, may be expected to have all standard reference works, secondary books, and bound newspapers; in addition, it is rapidly building up its collections of manuscripts. The library of the State Historical Society of Iowa, also at Iowa City, is rich in materials for the study of the state's history. The Iowa State University library at Ames is especially good for research in government publications having to do with engineering, atomic energy, and all phases of agriculture. The library of the Iowa State Department of History and Archives at Des Moines has a fine collection of official state publications as well as the state government's archival deposits. At least four of its manuscript collections are worthy of notice: the William Boyd Allison papers, the Grenville M. Dodge papers, the Albert B. Cummins papers, and the Emerson Hough papers.

taxation and supervised by state authorities. Attendance is required through the age of 16 and a school year of at least 9 months is mandatory.

Inadequate variety in the curriculum offered by small schools, especially at the secondary level, has led since the mid-1950's to the combining of many rural and urban districts into larger community districts with greater school populations. Thus the total number of school districts was re-

1960 Final Census 2,757,537; 1965 Est. 2,760,000

All figures available from 1960 final census are supplemented by local official estimates.

The libraries at the State College of Iowa and Grinnell College are above average in quality. Excellent municipal libraries may be found in Des Moines, Dubuque, Burlington, and Sioux City.

Major Health and Welfare Agencies and Institutions.—Iowa's health services are provided at the state and local levels of government. The state health commissioner and the Board of Health provide such services as control of cancer and communicable diseases, heart disease studies, maternal and child health care, nutrition programs, public health education, vital statistics, and licensure of medical professions. There are state and local programs for aid to the blind. Rehabilitation for the physically handicapped is a function of the state superintendent of public instruction. The Board of Regents, in its program of higher education, trains physicians, dentists, and nurses. The extensive services of the university hospitals in Iowa City are available to patients from all of Iowa.

The three-man Board of Control was created in 1898 to manage state penal, mental health, and child care institutions, which now number 14 (including an old soldiers' home at Marshalltown). Four state mental health institutions are situated at Independence, Cherokee, Mount Pleasant, and Clarinda, and there are two homes for feeble-minded persons at Woodward and Glenwood. Iowa now employs a mental health specialist to counsel these six institutions and to coordinate work with the University Medical School. Child care agencies include an orphanage at Davenport and a home for older children at Toledo. A hospital for tubercular patients has been transferred from the Board of Control to the Board of Regents so that it is associated with the medical and hospital services of the university. County and city health officials enforce state laws on the local level.

The three-member Board of Social Welfare was created in 1937. It administers state and federal laws dealing with social security, provisions for the aged and the blind, and child welfare. County welfare boards and local social workers provide aid and supervision. The University of Iowa now has a school of social work, so that some social workers are trained in the state.

Penal System and Institutions.—The Board of Control supervises the five state institutions related to correction and punishment. The men's penitentiary was established at Fort Madison in 1839. A men's reformatory is located at Anamosa and a women's reformatory at Rockwell City. Training schools for boys and girls are situated at Eldora and Mitchellville. The governor of Iowa is aided in enforcing the laws of the state by the attorney general and the commissioner of public safety, and in emergencies by the National Guard. The 99 county sheriffs enforce laws in the counties and are in charge of the county jails.

For additional statistics on education and welfare, consult *THE AMERICANA ANNUAL*.

5. ECONOMIC ACTIVITIES

Iowa's economic history began with the fur traders who canoed upstream on the tributaries of the Mississippi River to trade "white man's goods" for pelts. Since Iowa was covered principally with prairie grass, the number of pelts obtained was not great, and the fur trader was an ephemeral visitor on the landscape. The dis-

covery of lead in northeast Iowa (known as the "Lead Mines of Spain" when the area was under Spanish control from 1762 to 1800) led to the development of a brief but rather important mining economy.

Most of the early settlers in Iowa made a living from agriculture; the life of the homesteaders was on a subsistence basis and remained so for many years. After railroads were built to the river cities, the pioneers could sell wheat, corn, salt pork, and hams, and buy cloth, salt, guns, ammunition, and a great variety of items in exchange.

The dominant and basic driving force of Iowa's economic history since these early times has continued to be agriculture. Experiments with crop rotation, animal and plant breeding, feeding formulas for livestock, and mechanization have increased the yields of feed grains per acre and the quality of livestock raised. The State Agricultural College and the 4-H clubs have been leaders in the improvement of farm products and farm living. Only in recent years has the value of manufactured products exceeded that of agricultural products brought to market, and manufacturing remains closely allied with agriculture in the state.

Income.—The median income in Iowa in 1950 very nearly matched the national median for the same year. Between that time and the early 1960's, rises in the average personal income in Iowa lagged behind the national average, due in large part to a cost-price squeeze which affected farm profits. Percentage distribution of Iowans in the various income brackets approximates the percentage distribution in the nation.

O. V. Gordon

Knee deep in corn, this farmer can testify to the fact that Iowa leads all states in production of the grain.

Labor Force.—About 325,000 Iowans, or less than 30 per cent of the working labor force, were engaged in agricultural pursuits in mid-1962.

Agriculture's share of the total labor force steadily declined after 1950, since farm units were getting larger in size and fewer in number and mechanization was making possible greater production with proportionately less manpower.

Of the employed nonagricultural labor force of some 850,000 in July 1962, 25 per cent were engaged in wholesale or retail trade, 25 per cent in manufacturing, and 17 per cent in government services. About a quarter of the nonagricultural workers were members of unions.

Agriculture.—The basis of Iowa's agricultural importance is the large extent of its productive soil. About 25 per cent of the Grade I land in the United States is in Iowa. More than 62 per cent of the land area of the state is in harvested crops; the largest percentage in the nation, and more than 95 per cent is in farms, the average size of which had risen to nearly 200 acres in the early 1960's. The average value of Iowa farmland had, by 1962, reached over \$241 per acre, with all farmlands and buildings valued at about \$8 billion.

The state has traditionally led all others in the production of corn, the annual harvested value of which often approaches \$1 billion. Oats and soybeans are also important. One of the chief uses of Iowa crops is the nourishment of hogs and cattle. The cash income from livestock and livestock products may exceed \$2 billion in a good year, with cattle and hogs each accounting for about 40 per cent of the total, most of the balance being provided by sales of dairy products, eggs, broilers, and sheep. Marketed crops may bring additional cash income of \$300 to \$600 million, of which corn normally accounts for more than half and soybeans for over a quarter.

North central Iowa, totaling 22 counties, is the cash grain area. In this section, land values are higher than in other areas of the state. A high percentage of land is in feed grain, with

a tendency toward two-year rotation and a low percentage in hay and pasture. Corn, oat, and soybean sales total from 40 to 60 per cent of farm sales. Hogs are of less relative importance than cattle. The area is predominantly level, with deep, rich prairie soil. A considerable number of drainage ditches are necessary since this glacial plain is poorly drained.

The dairy region includes 18 counties in northeast Iowa. Even in this section, however, dairy receipts are exceeded by receipts from either hogs or cattle. About 40 per cent of the area is in pasture and hay since much of this land is too hilly for row crops.

Agriculture in the remaining counties is classified as crop and livestock combination. A three-, four-, or five-year rotation plan assures ample feed grains and hay for hogs, sheep, and cattle. Many lambs and feeder cattle are shipped in from Western ranges to be fattened on Iowa-grown grain and hay; pigs are farrowed on the farms. Receipts from the sale of hogs, cattle, and sheep constitute the major source of farm income.

Lumbering.—There are 2.6 million acres in Iowa (over 7 per cent of its area) classified as commercial forest land. Some 1,000 sawmills were operating in the late 1950's, nearly a quarter of them on a full-time basis, and were producing about 90 million board feet annually. Chief species of saw timber are oak, elm, cottonwood, maple, basswood, and black walnut. Iowa forests and wood products bring an annual income of \$18 million to \$20 million. Eight state forests are under the direction of the State Conservation Commission.

Mining.—Iowa ranked 30th in the nation in value of mineral production in 1961, producing only about 0.5 per cent of the national total. Cement (valued at over \$41 million in 1960) is the most important mined resource, followed by stone other than for cement, sand and gravel, gypsum, and coal. Cement plants are located at Mason City, Davenport, Des Moines, and West Des Moines. Stone for purposes other than the manufacture of cement is quarried almost exclusively in eastern Iowa. Gypsum, in the production of which Iowa ranks third in the United States, is mined in four strip mines located near Fort Dodge. Other deposits of gypsum are known to exist in southern and southeastern Iowa, but at a depth that has heretofore made mining economically unfeasible. Most of Iowa's 300 gravel pits are located in the north central region; those in the south are found along major streams. Coal is mined in the south central counties, about 80 per cent of it by the strip method. Production declined from over 9 million tons in the peak year of 1917 to less than 1.1 million tons in 1961.

Manufacturing.—Most of Iowa's manufacturing is farm-centered, processing products that come from the farms or making equipment used on them. The principal processed foods are meat, dairy, and grain-mill products; processing meat furnishes employment for more than half of the persons engaged in manufacturing food and kindred products. Tractors, combines, corn pickers, and hay balers are a few of the machines manufactured for use on the farms.

Although there were about 3,700 manufacturing plants in the state in 1960, only a small percentage of them employed more than 50 workers. Des Moines, Cedar Rapids, and Waterloo, in the order

Assembly line of a leading tractor plant, at Waterloo. Iowa manufactures much equipment for its own farms.

John Deere Waterloo Tractor Works

A huge ingot comes off the hot line of the largest aluminum rolling mill in the United States, at Davenport.

listed, are the leading manufacturing cities. Some plants are nationally known: for example, Iowa had the largest pork processing business, cereal plant, wheel tractor manufacturing plant, washing machine industry, fountain pen manufacturer, and aluminum rolling mill in the United States in 1958. The state has benefited from the expansion of manufacturing in the nation and from the trend toward decentralization; many out-of-state industries now operate one or more factories in Iowa. The total annual output of manufactured products in the state passed the \$4 billion mark in 1955 and the \$5.25 billion mark in 1960. Adjusted value added by manufacture in 1960 was estimated at about \$1,800 million, of which nearly 40 per cent was in food and kindred products and 30 per cent was accounted for by the manufacture of machinery, much of it for farm use.

Power.—Hardly more than a quarter of the potential water power in the state had been developed by 1960, and power was not being produced at all of the 25 dams licensed for its production. About a tenth of the electrical energy in Iowa is hydroelectrically produced, the greatest single source being the Keokuk plant on the Mississippi.

Banking and Insurance.—Some 100 national banks and more than 500 state banks, with total assets of over \$3 billion, operate in Iowa. There are also numerous federal and state mortgage and loan associations, private banks, credit unions, and small loan companies. Insurance is a major business; nearly a score of companies are under charter from the state and there are many fraternal beneficiary associations, fire insurance companies, casualty insurance companies, and branch offices of national insurance companies.

Trade.—Iowa has always lagged behind the United States average in the excess of wholesale over retail sales. This is due in part to the high percentage of agricultural activity, and in part to the large wholesale markets that border Iowa—Chicago, Minneapolis-St. Paul, Omaha, Kansas City, and St. Louis. More than half the total sales of wholesale establishments in the

state are concluded in the 14 largest cities. Because of the importance of agriculture in the economy, food purchases constitute a smaller proportion of total retail trade than in the United States generally, while purchases of farm implements, hay, grain, livestock feeds, and petroleum products play a larger part in the retail turnover.

The only foreign trade center in Iowa is in Cedar Rapids; 10 per cent of the city's labor force earns its livelihood, directly or indirectly, by foreign trade. During the 1950's, about \$25 million worth of goods were exported annually by some 50 firms.

W. A. Scheaffer Pen Company

In plant at Fort Madison, worker examines strip of 14-carat gold from which pen points have been stamped.

For additional statistical data on the economic life of Iowa, consult *THE AMERICANA ANNUAL*.

6. TRANSPORTATION AND COMMUNICATIONS

Transportation.—Rivers and trails formed the basis for early transportation in pioneer Iowa. Canoes, barges, keelboats, and steamboats were early modes of transportation on the Mississippi, the Missouri, and inland rivers; Indian trails, military roads, and stagecoach routes were important before the construction of the railroads. At least five railroads reached the Mississippi River from the East only to be halted for lack of bridges and financial support. Several of the lines had been laid partially across the state at the outbreak of the Civil War, and the Northwestern became the first to span the state during the postwar period. Railroads reached their peak of construction from 1880 to 1890; highways and automobiles, private and commercial air travel,

and renewed river traffic have been added to Iowa's transportation facilities in the 20th century.

Water transportation along the Mississippi is becoming increasingly important in the 20th century because of the series of dams and the nine-foot channel. Coal, oil, and machinery move northward, and farmer's grains move downstream to processors and consumers. The oldest lock on the Mississippi River, at Keokuk, was replaced in 1958 by a new one that expedited barge traffic. An eight-foot channel on the Missouri has resulted in increased freight movement on that river.

In 1960, 24 railroads operated on some 9,500 line miles of railway track in the state of Iowa. Because the pioneers moved westward, east-west traffic became and has remained most convenient, but branch lines were added to provide a network of railways which serve the whole state. At one time it was claimed that no Iowa town was more than 12 miles away from a railroad. In the 1950's considerable railroad passenger service was eliminated. The last electric streetcar to serve the state was discontinued in 1958.

There are more than 200 airports in the state; in the early 1960's some 2,000 airplanes were registered by the Iowa Aeronautics Commission, and about 10,000 Iowans held pilots' licenses. Four major airlines maintained airports, and additional air service was provided by feeder lines.

Serving automotive transportation are over 110,000 miles of roads classified as either state primary roads, state secondary roads, county truck roads, or county local roads. Iowa has a heavy road expenditure program (over \$100 million per year), partly because there is less waste land here than in most states. Each section of land is bordered by a road, so that every farmer has transportation facilities. A major effort in highway construction was made in the 1920's, and a long-range highway-widening program was inaugurated in 1955. Federal funds are providing

impetus for the construction of one east-west freeway across the state and two north-south freeways. Local roads are varied in quality, but all county roads have some type of all-weather surfacing. Much of the state road income is derived from a six-cent-per-gallon fuel tax, motor vehicle registration fees, and a use tax on automobiles and equipment.

Communications.—The state has no regulatory agency to supervise communications. In 1961, 46 daily newspapers and some 400 others were published in Iowa. The *Des Moines Register* and *Des Moines Tribune*, a morning and an evening daily, have statewide circulation, and the monthly magazine *Better Homes and Gardens*, published in Des Moines, is read throughout the country. There were 82 AM radio stations in 1962, 14 FM stations, and 13 television stations (2 UHF and 11 VHF). Business and residential telephones in use in the state in that year numbered more than 1.2 million.

7. CULTURAL LIFE

Cultural activities are largely the monopoly of the educational institutions of the state, both publicly and privately supported, though in some cases municipal forces join in the support of symphony orchestras and choral organizations. Des Moines, Waterloo, Sioux City, Davenport, and Burlington are outstanding for this kind of cooperation between "town and gown." A very enthusiastic art movement has swept the state in the last 20 years; all the larger cities and many smaller cities and towns have leagues or associations which support galleries, sponsor exhibitions, and conduct training classes. The Des Moines Art Center is most notable in this respect.

The little theater movement is most active in Des Moines, Waterloo, Sioux City, and Davenport. Nearly every town and city in the state has an organization for the presentation of concert artists; several of them bring performers of world fame to their audiences.

8. PLACES OF INTEREST

A number of state parks provide facilities for recreation and the appreciation of nature's beauties but little of educational value or historical interest. A national park, the Effigy Mounds National Monument, near Marquette, possesses real interest for both the casual traveler and the student of archaeology. A privately endowed museum at Cherokee, the Sanford Museum of Natural History, contains artifacts from a site known as the Mill Creek excavations.

The Hoover Birthplace Park at West Branch contains buildings associated with the birth and early life of Iowa's only presidential son; a library-museum, opened in 1962, houses valuable papers from the Hoover collection formerly at Stanford University and displays materials relating to Mr. Hoover's career.

The Bily clocks, an unusual collection of hand-carved clocks of all sizes and styles, are housed at Spillville. This exhibit, together with the little town's associations with the memory of Anton Dvořák's residence there, brings thousands of visitors annually.

9. FAMOUS MEN AND WOMEN

Iowans who have achieved distinction in various fields of activity include the following: Herbert Clark Hoover (born in West Branch, 1874–), 30th president of the United States; Henry Agard Wallace (Adair County, 1888–), former secretary of agriculture and vice presi-

Herbert Hoover's birthplace, at West Branch.

(Right and below) O. V. Gordon

dent of the United States; Harry Lloyd Hopkins (Sioux City, 1890-1946), public official and administrator; Edwin Thomas Meredith (Avoca, 1876-1928), secretary of agriculture; William Daniel Leahy (Hampton, 1875-1959), naval officer and presidential adviser; William Ashley (Billy) Sunday (Ames, 1863-1935), evangelist; William Frederick (Buffalo Bill) Cody (Scott County, 1846-1917), scout and showman; Newell Dwight Hillis (Magnolia, 1858-1929), Congregational clergyman; and Glenn L. Martin (Macksburg, 1886-1955), airplane designer.

In the field of literature, the state is represented by Bess Streeter Aldrich (Cedar Falls, 1881-1954), novelist; Thomas Beer (Council Bluffs, 1889-1940), novelist and biographer; Richard Pike Bissell (Dubuque, 1913-), novelist and playwright; Ellis Parker Butler (Muscatine, 1869-1937), humorist; Marquis William Childs (Clinton, 1903-), journalist and author; George Cram Cook (Davenport, 1873-1924), novelist and playwright; Thomas William Duncan (Casey, 1905-), novelist; Paul Hamilton Engle (Cedar Rapids, 1908-), poet; Susan Glaspell (Davenport, 1882-1948), novelist and Pulitzer Prize winner; James Norman Hall (Colfax, 1887-1951), author; Harry Hansen (Davenport, 1884-), editor, critic, and war correspondent; James Schell Hearst (Cedar Falls, 1900-), poet; Emerson Hough (Newton, 1857-1923), novelist; MacKinlay Kantor (Webster City, 1904-), novelist and short story writer; Honoré Willies Morrow (Ottumwa, 1880?-1940), novelist; Philip Duffield Stong (Keosauqua, 1899-1957), novelist; Ruth Suckow (Hawarden, 1892-1960), novelist; Carl Van Vechten (Cedar Rapids, 1880-), novelist; and Margaret Wilson (Traer, 1882-), novelist and Pulitzer Prize winner.

In the field of music, painting, and sculpture the best-known names are Marvin Cone (Cedar Rapids, 1891-), painter and sculptor; Abastenia St. Leger Eberle (Webster City, 1878-1942), sculptor; Sherry Edmundson Fry (Creston, 1879-), sculptor; Nellie Verne Walker (Red Oak, 1874-), sculptor; Meredith Willson (Mason City, 1902-) conductor and composer; and Grant Wood (Anamosa, 1892-1942), painter.

10. HISTORY

Prehistory.—Serious anthropological and ethnological studies have only recently begun in the Iowa region. Finds in the northeast (the most typical now preserved in Effigy Mounds National Park) and in gravel pits near Turin in western Iowa are still undergoing study. It cannot be disputed, however, that the land was once occupied by a population different in its habits from the Indians encountered by the pioneers. Several distinct cultures have been tentatively identified from the traces left by these "mound builders," who may or may not have been direct ancestors of the later Indians.

Discovery and Early Possession.—The first recorded sight of the future state by white men occurred on or about June 17, 1673, when Father Jacques Marquette and Louis Jolliet (or Joliet) arrived at a point on the Mississippi opposite the mouth of the Wisconsin River, a spot commemorated today by a nearby village named in honor of Marquette. Their journey continued southward, and they may have conferred with the Indians at the mouth of the Iowa River. Their discoveries gave France the basis of a claim to a vast region far beyond the seigniories of Quebec. Thus "Iowa" became, as a part of Louisiana, a dot on the map of Louis XIV's French Empire.

In 1763 the Louisiana portion of this empire was ceded to Spain and retained by her until 1800, when pressure from Napoleon forced its return to France. The only lasting evidence of the Spanish tenure is to be found in three land grants which later entered into court records. The first of these, in 1796, was to Julien Dubuque, who carried on extensive lead-mining operations near the site of the modern city which bears his name; another was to Louis Honoré Tesson, in 1799, near present-day Montrose; the last was to Basil Giard, in 1800, near present-day McGregor.

Territorial History and Admission to Statehood.—"Americanization" began after the Louisiana Purchase Treaty of 1803, making Iowa

part of the United States. The future state's first American benefactors may be said to have been Meriwether Lewis and William Clark; it is notable that the first white man buried on Iowa soil (near Council Bluffs) was a member of their expedition.

The region which became Iowa was first a part of the District of Louisiana, but under the jurisdiction of the governor of the Territory of Indiana. During this period a few courageous or desperate souls came into the area in spite of the Land Act of 1805, which forbade its settlement by whites. In 1812 it became a part of the Territory of Missouri and was greatly affected by that provision of the Missouri Compromise (1820) which forbade slavery forever in any part of the territory north of the line of 36° 30', except in Missouri itself.

After Missouri became a state in 1821, "Iowa" was officially neglected and ignored until after the Black Hawk War of 1832. The remainder of the Louisiana Purchase was assigned to Michigan Territory in 1834, and statehood for Michigan (1836) left the Territory of Wisconsin next in succession. In 1838, Wisconsin Territory was delimited to the area of the present state, and the remainder of the Purchase came onto the map as the Territory of Iowa. The capital was located first at Burlington, and after 1841 at Iowa City. The formal processes of admission to statehood were set in motion in 1844, and after a prolonged dispute over boundaries, the state was admitted in 1846.

Indian Affairs.—The earliest pioneers encountered several Indian tribes, most important of which were the Iowas, of Siouan stock, whose name came to be applied to the region. Subsequently the Sac and Fox Indians, the Potawatomi, and the Winnebagos moved or were moved into the area, yielding to the relentless westward pressure of the white man. By 1824 the Indians were compelled to cede a portion of land in the southeast as a "Half-breed Tract"; in 1832, following the defeat of Black Hawk and his Sac and Fox warriors, the "Black Hawk Purchase" secured a large area just west of the Mississippi to white settlement. In 1836, 1837, and 1842, the Sac and Fox agreed peacefully to three successive withdrawals from their lands and evacuated to Kansas, though some of them were later to return to settle on purchased lands in Tama County. The Potawatomi gave up their holdings in the southwest in 1846, and the Winnebagos left their lands in the northeast in 1848. The Sioux conceded their losing battle in 1851, but a few of their tribe returned in 1857 to perpetrate the massacre of Spirit Lake, which lives on in the recorded history of the state as well as in its legends.

Early Statehood.—The first state constitution (1846-1857) was a typical expression of the prejudices of frontiersmen, especially on the subject of banks and bankers. The capital was located at Iowa City; the first governor was Ansel Briggs. The vigorous leadership of Governor James W. Grimes secured a new constitution (1857) which, with amendments, still serves. The capital was moved to Des Moines the same year.

The era was one of growing tensions between slavery and antislavery forces throughout the nation. Iowans in great numbers moved into the new Republican Party, formed in 1854-1856 to oppose the expansion of slavery into new territories. Iowa Democrats, until 1854 the political

masters of the state, now found themselves facing the same dilemma as Democrats elsewhere in the North: to defend slavery and preserve party unity or to condemn it and split the party nationally. Some were willing to take the latter course; one Iowan, Benjamin M. Samuels, took a leading part in the division of the party at the Charleston (S.C.) convention in April 1860.

Civil War and Reconstruction.—During the Civil War, Iowans contributed a fair share toward the support of the Union cause in military manpower, economic production, and financial and material gifts and loans. Some 80,000 men went out from the state to fight, and about 12,000 lost their lives. Of immeasurable importance was the staunch support given to President Abraham Lincoln's war effort by the dominant Republican Party in Iowa. In 1862 and 1864, as other states wavered or fell away, Iowa Republicans rolled up safe majorities. Their opponents, meanwhile, compounded their political difficulties by dividing into War Democrats and Peace Democrats, neither of whom could wholly escape the "party of treason" stigma.

This political situation carried over into the Reconstruction period, when nearly all Iowa Republicans became pronounced Radicals. It is hardly an exaggeration to say that the advantage gained by the Republicans during the war and Reconstruction guaranteed them a supremacy which only a political "revolution" could destroy.

Agrarian Radicalism.—Beginning in the closing months of the Civil War, a deflation in the national economy occurred, destined to last until the end of the century. This naturally brought forth a variety of proposals designed to end or alleviate the distress. Since these proposals were often presented with evangelical fervor by eccentric figures who belonged to minority groups, they were lumped together under the prejudicial label "agrarian radicalism."

The remedies proposed were: (1) a greater use of greenbacks (unsecured paper money); (2) free silver (unlimited coinage of silver dollars); (3) regulation of railroads (popularly known as "Grangerism"); and (4) antimonopoly measures. All resulted in compromises.

The Greenback movement began in 1864, when an Iowan, Henry Clay Dean, a Peace Democrat usually held up to ridicule, published *Crimes of the Civil War* as a call for unlimited issues of greenbacks. The Resumption Act of 1875 (providing for the redemption of greenbacks in gold) was a crushing blow to the movement, and it petered out during the next 10 years, though an Iowan, James B. Weaver, ran for president as a Greenbacker in 1880. The free silver agitation rose to its height after the so-called "Crime of '73," when Congress struck silver dollars from the list of mintable coins. An Iowa senator, William Boyd Allison, helped to compromise the matter by providing the key amendments to the Bland-Allison Act (q.v., 1878). By his plan, a limited number, whatever number provided by the purchase of \$2 million to \$4 million worth of silver ore, as determined by the secretary of the treasury, were to be coined into silver dollars each month. This measure was inadequate according to the prevailing view in Iowa. Free silver died in the election of 1896 and in the economic upturn of the closing years of the 19th century.

Regulation of the railroads and antimonopoly legislation were closely related. The Granger

movement was not purely rural in origin or application, and regulation of the railroads was strongly desired in Iowa by the merchants of the Mississippi River towns who suffered from the long haul and pooling policies of the roads. Iowa's law of 1874 is frequently mentioned as the first attempt at state regulation. The state's activities in this field culminated in the positive program of Governor William Larrabee (1886-1890).

The Populist (People's Party, q.v.) movement of the 1890's was an expression of all these efforts at reform and uplift. James B. Weaver was again the third-party presidential candidate in 1892, although the Populists were not very strong in his home state.

Progressive Era.—The blend of reformism and social progress known as Progressivism invaded both major political parties in the early 1900's, but was most notable, especially in Iowa, in the Republican Party. Among the leaders of this movement were Albert Baird Cummins, governor (1902-1908) and United States senator (1908-1926), and Jonathan Prentiss Dolliver, United States senator (1900-1910). In Iowa the chief accomplishments were the anti-railroad-pass law, the direct primary law for senatorial nominations, better support for education, better penal laws, and stricter regulation of railroads and insurance companies.

World War I and the Agricultural Depression.—During the war years 1914-1918, American farmers were encouraged by economic factors and government persuasion to put all possible land into agricultural production. Iowa farmers responded enthusiastically and for a time enjoyed considerable prosperity. Prices of all farm produce rose to unheard of heights, and land values reached a peak which was not to be equaled again even in the 1950's. All too often, however, land was bought on a mortgage plan.

When the war ended and the governments of the world retired from the markets, prices fell disastrously. Farm purchasers were unable to meet their payments, and many banks and insurance companies were forced into ruin or into desperate measures. A severe farm depression was a reality by 1920-1921 and dragged on through the remainder of the decade. Many proposals were brought forth for the relief of agriculture, the principal one being the bill sponsored by Senator Charles L. McNary of Oregon and Congressman Gilbert N. Haugen of Iowa, the latter a long-time spokesman for agriculture in Congress. The legislation, designed to raise the domestic price of farm products above the world price, twice passed Congress but was vetoed each time by President Calvin Coolidge. The Farm Marketing Loan Board Act (1930), providing for government purchase and orderly marketing of farm produce, was a failure in practice. Many Iowans were brought to the point of desperation, as reflected by such acts as the dumping of milk trucks and the unpardonable mistreatment of a jurist who had merely done his duty as he saw it.

New Deal, World War II, and After.—In the elections of 1932, for the first time since 1849, the Democrats elected a governor in a race against an undivided Republican Party (the latter had been divided by a dispute over prohibition in 1889 and 1891). The Democratic national administration acknowledged the importance of the agricultural problem by selecting a successful Iowa agricultural journalist and plant breeder, Henry A. Wallace, as secretary of agriculture. Measures

were introduced to bring supply and demand more closely into line. The question of the wisdom of such policies was taken into the political arena, and by 1939 the Republicans had returned to power in the state.

More than a quarter of a million Iowans served in the armed forces during World War II. Wartime demands for foodstuffs brought new prosperity, and the much-feared postwar depression failed to materialize, prices and living conditions finding a peacetime level well above that of 1939. Inflation became a serious problem in the 1950's when the prices of the manufactured goods needed by farmers rose faster than the prices which they could get for their agricultural produce. The consequent squeeze on profits hastened the trend toward larger farms and greater mechanization, as farmers sought to control costs by increasing operating efficiency. This process continued unabated in the early 1960's.

Democrat Hershel C. Loveless won the governorship of Iowa in 1956, ending nearly two decades of Republican rule. Republicans recaptured the executive office in 1960 with the election of Norman A. Erbe, but lost it to another Democrat, Harold E. Hughes, in 1962. Meanwhile, other state house elective offices, as well as the General Assembly and the state's Congressional delegation, remained predominantly Republican.

LELAND L. SAGE,
ERMA PLAETHN,
HERMAN NELSON,
State College of Iowa.

IOWA, State College of, a coeducational professional college at Cedar Falls, Iowa, offering training for all types of teaching positions in the public schools. The institution is fully accredited and is governed by a nine-member, governor-appointed Board of Regents. It offers B.A. degrees in teaching and in the liberal and vocational arts, the M.A. degree in education, and a sixth-year program leading to a specialist in education degree. The school has a 470-acre campus and 20 major buildings, including a library housing nearly 200,000 volumes.

Established in 1876 as the Iowa State Normal School, it was renamed the Iowa State Teachers College in 1909. Under that name, the institution attained a national reputation as a leading college in the field of teacher education. The name of the college was changed to State College of Iowa in 1961, when it began to offer the B.A. degree in the liberal and vocational arts for students not planning to teach. The college-operated Malcolm Price Laboratory School enrolls about 700 children from nursery through high school and is recognized as one of the nation's finest. State College athletic teams, known as the "Panthers," compete in all major intercollegiate sports; the school colors are purple and gold; and the

school song is the *SCI Loyalty Song*. Average annual enrollment exceeds 4,500.

LOREE WILSON,
State College of Iowa.

IOWA, State University of, a coeducational, state-supported institution of higher learning located in Iowa City, Iowa. It was founded in 1847 by the First General Assembly of the State of Iowa and began to give instruction in 1855. The university is governed by the State Board of Regents, whose nine members are appointed by the governor, subject to confirmation by the Senate. The academic divisions are the colleges of Liberal Arts (including schools of journalism, religion, fine arts, and social work), Law, Medicine, Dentistry, Pharmacy, Nursing, Engineering, Education, and Business Administration, and the Graduate School. Degrees through the doctorate are conferred.

Among the other divisions of the university are the Agricultural Law Center, Institute of Agricultural Medicine, Institute of Hydraulic Research, Bureau of Labor and Management, Bureau of Business and Economic Research, Institute of Public Affairs, Iowa Center for Continuation Study, Iowa Institute of Gerontology, Iowa Urban Community Research Center, and the Extension Division. There are 1,000 beds in the hospitals comprising the university's medical center. State patients are brought to Iowa City from any point in Iowa by means of an ambulance system.

Students attend classes on a campus that covers some 1,330 acres. The University Library system contains more than one million volumes. Among the library's special collections are an extensive Leigh Hunt collection, an Abraham Lincoln collection, and a collection of original cartoons by Jay Norwood ("Ding") Darling. The school colors are old gold and black and the athletic teams are known as the "Hawkeyes." The school songs are *On Iowa* and *Iowa Fight Song*. Annual enrollment averages about 12,000.

KEN DONELSON,
State University of Iowa.

IOWA CITY, city, Iowa, the seat of Johnson County, in the east central part of the state. It is on the Iowa River, about 120 miles east of Des Moines and 60 miles west of Davenport. Situated on federal and state highways, the city also has an airport. Iowa City is located in a rich agricultural area. Its industries include the manufacture of soap and drug products, toothbrushes, frozen foods, and animal feeds. The State University of Iowa (see IOWA, STATE UNIVERSITY OF), whose campus is divided into two sections by the river, plays a major part in civic life and has contributed to the development of Iowa City as an important cultural, medical, and industrial center. The city is the site of the state school for crippled children, state general and mental hospitals, a veterans hospital, and the State Historical Society Library.

Platted in 1839, Iowa City was established by the Iowa Territorial Legislature. It was the capital of the territory from 1841 and of the state from 1846 until 1857, when the seat of government was moved to the more centrally located city of Des Moines. The original capitol building, a stone structure in the Doric style erected in 1840, still stands, serving now as the administrative center of the university. For some time

after 1856, Iowa City was the western terminus for a pioneer railroad, from which immigrants traveling west started out with handcars or covered wagons. Earlier, during the winter of 1846, Brigham Young's band of Mormons found sanctuary here en route from Nauvoo, Ill., to the Utah Territory. A prominent 20th century resident has been Dr. James Van Allen, head of the university's physics department, after whom the Van Allen radiation belts were named. Iowa City is governed by a city manager. Pop. 33,443.

JOYCE E. NIENSTEDT,
Librarian, Public Library of Iowa City.

IOWA FALLS, city, Iowa, in Hardin County, on the Iowa River, 85 miles by highway north of Des Moines. It is served by three railroads and has a municipal airport. It is in an agricultural area producing soybeans, corn, oats, hogs, cattle, and poultry. Industries and trade are represented by feed milling and processing, construction, production of concrete, and leather goods manufacture. Ellsworth Junior College is located here, and the city boasts a 40-acre park system, a public library, a hospital, a radio station, and a community theater. First called Rocksylvania, it was founded in 1854 and incorporated in 1869 as Iowa Falls, taking its name from a local waterfall. It has a council-manager form of government. Pop. 5,565.

LUCILE MILLER.

IOWA INDIANS or **IOWAY INDIANS**, *i'ō-wā* (Siouan, meaning uncertain; possibly *Ayuhwa*, "sleepy ones" or *Aiyuwwe*, "marrow-eaters"). A small tribe of the Siouan linguistic family related to the Oto and Missouri, all of which were at one time part of the Winnebago tribe. The Iowa eventually separated from this group and settled in the state which later adopted their name. Never a large tribe, they probably numbered 1,000 at most. In the early 1960's, some 550 lived in Kansas and 125 in Oklahoma, on lands given to them by treaty.

FREDERICK J. DOCKSTADER.

IOWA RIVER, river, Iowa. It rises in Hancock County, near the Minnesota state line, and flows southeast into the Mississippi River, 30 miles north of Burlington, Iowa. It is 291 miles long and navigable to Iowa City (some 80 miles).

IOWA STATE UNIVERSITY OF SCIENCE AND TECHNOLOGY, a coeducational, land-grant institution at Ames, Iowa, known before 1959 as the Iowa State College of Agriculture and Mechanic Arts. It occupies a campus and recreation area of nearly 1,000 acres, landscaped into a naturalistic park in the city of Ames. About 8,000 additional acres are operated as experimental areas near Ames and in various sections of the state. The university consists of the colleges of Agriculture, Engineering, Home Economics, Sciences and Humanities, and Veterinary Medicine, and the Graduate College. The latter is one of the nation's largest graduate colleges specializing in science. The University Library at Ames houses over 500,000 volumes.

Approximately a third of the annual operating budget of the university is allocated to research conducted in the Agricultural and Home Economics Experiment Station, the Engineering Experiment Station, the Industrial Science Research Institute, the Veterinary Medical Research Insti-

tute, and the Institute for Atomic Research. An integral part of the Institute for Atomic Research is the Ames Laboratory of the United States Atomic Energy Commission, a major basic research laboratory employing about 700 persons.

The university was chartered by the Iowa General Assembly in 1858 as the State Agricultural College and Model Farm. It graduated its first class in 1872. The school now offers B.S., M.S., Ph.D., professional, and teaching degrees. The university colors are cardinal and gold and its athletic teams, nicknamed the "Cyclones," compete within the "Big Eight" (Missouri Valley Intercollegiate Athletic Association). Annual enrollment averages about 11,000; it includes a heavy enrollment in engineering, as well as the largest home economics program and largest undergraduate enrollment in agriculture in the world.

ROBERTA F. VANCE.

IPECAC, *ip'ê-kāk*, a drug consisting of the dried roots and rhizomes (horizontal underground stems) of certain plants of the genus *Cephaelis* (madder family, Rubiaceae) of tropical America. Two species, *C. ipecacuanha* (Rio or Brazilian ipecac) and *C. acuminata* (Cartagena, Nicaragua, or Panama ipecac), are recognized as official in the United States pharmacopoeia. Although the drug had long been used by certain South American Indians, it was not introduced into European medicine until the late 17th century. Its original use was for treatment of dysentery, for which it is now seldom used; it is effective against only amebic—not bacillary—dysentery. Today, ipecac is employed mainly as an emetic and an expectorant, especially in the treatment of certain respiratory affections. It may be administered in powder or tablet form or in various fluid forms, most commonly as syrup of ipecac. The active ingredients are several alkaloids, principally emetine and cephaeline. Some ipecac is cultivated in India and Malaya.

JOHN W. THIERET.

IPHIGENIA, *if-i-jê-ni'ā*, in Greek mythology, a daughter of Agamemnon and Clytemnestra. Her father, who had offended the goddess Artemis, was required to sacrifice Iphigenia to secure the release of the Greek fleet from Aulis, where it had gathered prior to the Greek attack on Troy. At the moment of sacrifice, Artemis, who suddenly relented, substituted for Iphigenia on the altar a beautiful hind and conveyed the girl in a cloud to distant Tauris (now the Crimea), where she became the priestess to the goddess.

At Tauris, in conformance with the law of the country, she was obliged to sacrifice every Greek who landed there. Among the visitors was her brother Orestes, who came to obtain the Taurian image of Artemis as an expiation for the murder of his mother (see CLYTEMNESTRA). Soon after his arrival, Iphigenia revealed her identity to him, and the two contrived to escape with the image and return to Greece.

The two episodes in the story were dramatized by Euripides, whose *Iphigenia in Aulis* and *Iphigenia in Tauris* are the most common sources for the legend. The Aulis episode was later treated by Jean Jacques Racine and Christoph Willibald Gluck (see IPHIGÉNIE EN AULIDE); the Taurian episode, by Gluck (see IPHIGÉNIE EN TAURIDE) and by Johann Wolfgang von Goethe, in the verse tragedy *Iphigenie auf Tauris* (1786).

IPHIGENIE EN AULIDE, ē-fē-zhâ-nē' ān-nôlêd', the name of a verse tragedy in 5 acts by Jean Jacques Racine and an opera in 3 acts by Christoph Willibald Gluck. Racine's drama was first presented at court in 1674 and to the public in the following year. Coming after such oriental subjects as *Bajazet* and *Mithridates*, *Iphigénie en Aulide* was a return to the classical world of *Andromache* (1667) and has been ranked among the author's best works. The plot follows the Euripidean drama (see **IPHIGENIA**), with one notable exception. Racine introduced the character of Eriphile, a captive of Achilles who accompanies Iphigenia to the Greek camp, and having fallen in love with Achilles, warns the Greeks of her rival's attempt to flee on hearing her fate. Iphigenia is prepared for her death when Calchas announces that Eriphile fulfills the requirements of the sacrifice and is put to death in the place of Iphigenia.

Gluck's opera *Iphigénie en Aulide* was first produced in Paris in 1774 (see **GLUCK**; **OPERA—Gluck**) on a libretto by the Marquis Du Rollet. It also follows the general outlines of Euripides' tragedy, with an altered denouement. Achilles tries to save Iphigenia from the sacrifice but she, not wishing to see the hero disgraced, resolves to die. Just as the sacrifice is about to take place, Achilles is prepared to rescue Iphigenia by force of arms, but the goddess Artemis interposes, declaring herself appeased and the opera ends with Iphigenia and Achilles momentarily united before the latter leaves for Troy.

An arrangement of Gluck's *Iphigénie en Aulide* was made by Wagner and performed in Dresden in 1847. For Gluck's other opera based on the Iphigenia legend see **IPHIGÉNIE EN TAURIDE**. Other operas on the Aulis events of the legend were composed by Antonio Caldara (1718); Karl Heinrich Graun (1748); and Luigi Cherubini (1788).

IPHIGENIE EN TAURIDE, ē-fē-zhâ-nē' ān tô-rêd', an opera in 4 acts by Christoph Willibald Gluck, with a text by Nicolas François Guillard, first performed in Paris in 1779. In the operatic "war" between Gluck and the Italian composer, Niccolò Piccini, both composers were commissioned to write an opera on this subject and Gluck's, produced first, established his position as the leading opera composer in Paris.

The plot is substantially that of the original legend with minor variations (see **IPHIGENIA**). At the end, Pylades escapes and returns just as the Taurian king is about to sacrifice both brother and sister, stabs the king, and the three of them sail away in safety. Among the several other composers who set this story to music are André Campra (1704); Tommaso Traetta (1763); and Baldassare Galuppi (1768).

IPPOLITOV-IVANOV, ĩp-pŭ-lyě'tóf-ĩ-vâ'nóf, Mikhail Mikhailovich, Russian composer: b. Gatchina, near St. Petersburg, Nov. 19, 1859; d. Moscow, Jan. 28, 1935. In 1881, to avoid confusing his real name, Ivanov, with a music critic of the same name, he added his mother's name to his own. A student of Rimski-Korsakov in St. Petersburg he made his debut there as a composer and conductor in 1883, and for ten years at Tiflis in the Caucasus he directed the music school, conducted at the Imperial Theater, and studied Georgian folk music, whose influence on his musical style has linked him with the Russian National

School. After 1893 he taught and composed in Moscow. Ippolitov-Ivanov's compositions include the operas *Ruth* (1887), *Azra* (1890), *Ole from Nordland* (1916), and the completion of Musorgski's opera *Marriage* (1931); one symphony (1907); many orchestral pieces, of which the *Caucasian Sketches* is the most popular; and works for chamber and vocal groups. Complying with the spirit of the Soviet regime, he also composed a revolutionary opera *The Last Barricade* (1933-1934) and several songs and marches, some of which were used by the Red Army. He was the author of *The Science of the Formation and Resolution of Chords* (1897, in Russian) and *Fifty Years of Russian Music in My Memories* (1934; in English, *Musical Mercury*, New York, 1937).

IPSEN, ĩp's'n, Ernest Ludvig, lŏöth'vêg, American portrait painter: b. Malden, Mass., Sept. 5, 1869; d. Miami, Fla., Nov. 2, 1951. He studied at the Boston Museum of Fine Arts and the Royal Academy at Copenhagen, and is known for the many portraits of famous persons which hang in galleries and educational institutions throughout this country. Since 1923 a member of the National Academy, he won the Lippincott prize for his *Mr. Lauth and Bottles* at the Pennsylvania Academy of Fine Arts exhibition in 1936, and many other awards. Among his portraits are those of Elihu Root, Dr. Henry van Dyke, Chief Justice William Howard Taft, and General Robert E. Lee.

IPSWICH, ĩps'wĭch, city, Australia, in Stanley County, Queensland, on the Bremer River, 20 miles west-southwest of Brisbane. It is located in a thriving agricultural region, also favored with extensive coal deposits. It has iron foundries, woolen mills, and lumber yards. Pop. (1947) 26,218.

IPSWICH, county borough, England, a river port in Suffolk, on the Orwell River at its confluence with the Gipping, 10 miles northwest of Harwich and 68 miles northeast of London. The older parts of the town have narrow crooked streets, some of the old houses of which are ornamented with curious carved work. It contains numerous churches and benevolent institutions, a town hall, art museum, mechanics' institute, corn exchange and an ancient mansion of the Tudors. Of its educational establishments the principal is the grammar school founded by Cardinal Wolsey and endowed by Queen Elizabeth.

The Saxon Gypeswyk, Ipswich was also a Roman settlement, remains of which still exist. It was pillaged by the Danes in 991 and again in 1000. The modern city is a large industrial center, manufacturing railway supplies, agricultural implements, electrical equipment, nonferrous metals, feed cakes, and sugar. Pop. (1951) 104,788.

IPSWICH, town, Massachusetts, in Essex County, 28 miles northeast of Boston on the Ipswich River, state highways, and the Boston and Maine Railroad. Altitude 30 feet. Ipswich's major industry was the manufacture of hosiery until 1927, when the mills were closed and their machinery sold to Russia. Several minor industries now occupy the mill buildings. Ipswich is a popular summer resort and famous for its shellfisheries and Crane's Beach for swimming.

Among the landmarks of the town are the Whipple House (1640), the South Church (1748), and the John Heard House (late 18th century). Anne Bradstreet and Nathaniel Ward also were early residents.

The town was settled as Agawam (Aggawam) in 1633 by John Winthrop and a group of 12 pioneers. By the following year it was incorporated under the name of Ipswich (after Ipswich, England) by resolution of the Massachusetts General Court. As early as 1634 it had a meeting house. The town was one of those which offered stubborn resistance to the arbitrary taxation introduced under Governor Edmund Andros, and a number of its citizens were punished for this action. The Rebellion Tablet marks the spot where the townfolk gathered to protest the governor's oppression nearly 100 years before the American Revolution. The township includes Ipswich village (pop. 4,617), and since 1951 has been governed by a city manager. Population: 8,544.

IQUIQUE, ē-kē'kā, city, Chile, seaport and capital of Tarapacá Province on the edge of the Atacama Desert, about 250 miles north of Antofagasta. Since rain seldom falls, the water supply has to be piped from the oasis of Pica, a distance of about 60 miles.

Served by railroads and an airport, the city is a trading and manufacturing center with petroleum and sugar refineries, cement factories, and fish-canning plants. Nitrates are mined and shipped from nearby deposits; iodine and salt are also exported.

Founded in the 16th century, Iquique was almost entirely destroyed by earthquakes in 1868 and again in 1877. In 1879, during the War of the Pacific, the city was taken by Chile from Peru, and by the Treaty of Ancón (1883) the province of Tarapacá was ceded to Chile. Population: (1960) 50,655.

IQUITOS, ē-kē'tōs, city, Peru, river port and capital of the Department of Loreto, on the upper Amazon near the mouth of the Nanay River, about 1,200 air miles northeast of Lima; altitude about 350 feet. Ocean-going vessels drawing 14 feet ascend the Amazon to this point and the river is navigable for lesser craft for 425 miles farther up. It has regular steamship connection with Belém, Brazil, via Manaus, connecting there with steamers for the United States and Europe. There are also frequent sailings for all places on the larger tributaries of the Amazon, and small launches keep in touch with small settlements, some of them 400 miles from the Amazon.

Iquitos is the trade center for the entire area of Peru lying east of the Andes. The chief exports, based on produce of the surrounding area, are rubber, tobacco, cotton, timber, oil nuts, balata, and some raw hides. The city has machine shops, sawmills, shipyards, cotton gins, factories making straw hats and soaps (from cottonseed oil), and distilleries producing rum from sugarcane juice. In the territory surrounding the city, which is chiefly agricultural, the main crops are cotton, corn, tobacco, and rice. Cattle are raised, and some of the forest clearings have been turned into promising banana plantations.

Iquitos dates from 1863, when a settlement was founded on the site of a fishing village. Population: (1961) 57,777.

IRAN, ē-rān', is a Muslim country in the Middle East. Known in Europe for centuries as *Persia*, the country demanded official recognition as Iran in 1935, but since 1949 has accepted *Persia* as an official alternative.

The country is bounded by the Soviet republics of Armenia, Azerbaïdzhān, and Turkmen on the north, Afghanistan and Pakistan on the east, the Arabian Sea on the south, the Persian Gulf on the southwest, and Iraq and Turkey on the west. With a total area of 636,363 square miles, the country is more than one fifth the size of the United States.

According to the results of the first general census, taken in November 1956, the total population was 18,954,704 (1964 est., 22,860,000). Teheran (Tehran), the capital, had a population of 1,512,082 in 1956 (1960 est., 1,839,000). At the time of the 1956 census it was estimated that the average population density was about 30 people to the square mile. The greater portion of the population is concentrated in the western and northern sections of the country. In the desert area and much of the southeast, the population is sparse, the average being less than 10 persons per square mile.

The official flag of Iran has three horizontal bars—green, white, and red; on the white bar is a golden lion holding a sword in one upraised paw, with the rising sun behind its back (for

Coat of arms

picture, see FLAG). The national anthem, officially adopted in 1934, is entitled *Salām-i Shāhānshāh va Sorūd-i Rasmi-yi Melli-yi Irān* (*Greeting of the King of Kings and Official National Anthem of Iran*). The better-known first line is *Shāhānshāh-i mā zandeh bādeh* (*Long Live Our King of Kings!*).

Total	18,954,704		

Of the total population of over 22 million, more than half live in farming villages. Another fifth of the people lead nomadic or seminomadic lives as herders. The remainder—less than a third of the total—live in towns of 5,000 people or more. The greatest concentration of city dwellers is in Teheran.

Iranian society presents sharp contrasts. The people of the larger cities have adopted Western ways, while among the nomad herders tribal customs still prevail. Some parts of the country are almost totally isolated, and languages that are unrelated or only distantly related to Iranian (Persian) are spoken there. Gradually, however, the unifying force of education is reaching even the nomads. The country is also being more closely knit together by better communications and by the village cooperatives set up in the 1960's to assist peasant farmers to make better use of land they received in the reforms of the 1950's and 1960's. New industries have drawn many people to the cities, where traditional ways are giving place to Western customs.

In seeking to create a unified society, Iran has no need to develop a synthetic culture or history to bind its people together. The country has a continuous national history of almost 3,000 years. The Persian empire was one of the great empires of the ancient world. Persian art and literature were second to none in the Middle East, particularly during the period known in Europe as the Middle Ages. Islam is the religion of almost all the people. Although Persian is not the only language spoken, it is tending to prevail as the country is tied more closely together through expanding communications facilities and through the Iranian government's educational programs.

The process of unifying and modernizing Iran, begun by Reza Shah after World War I and continued by his son Mohammed Reza Pahlavi after World War II, is still in its early stages. It has been resisted, vehemently at times, by conservatives among religious and economically prosperous groups. But land reform and economic planning continue slowly to modify the traditional social pattern.

1. THE LAND

Over 90 percent of modern Iran lies on the Iranian plateau, which stretches from the Tigris-Euphrates river valleys on the west to the Indus Valley and Pamir "Roof of the World" on the east. In its eastern half, the plateau also comprises Afghanistan and Pakistani Baluchistan. This plateau is boldly outlined in the shape of the letter V by the high Zagros and Elburz mountain ranges. These ranges are tied together at the apex—in and beyond the province of Azerbaijan—in what the geographers call the "Armenian knot," to which are also connected the Anatolian and Caucasian mountains.

World Bank

Building roads in the mountains of Iran is an expensive undertaking, but vital to the country's development.

Mountains. The Zagros range of mountains, rising steeply from the Mesopotamian plain, runs southeastward parallel to Iraq and the Persian Gulf. Several peaks north of the head of the gulf reach more than 14,000 feet in height. The range then tapers off into the wastelands of Baluchistan opposite the Indian Ocean. The Zagros range, comprising the mountains of Kurdistan, Luristan, Bakhtiari, Fars, and Baluchistan, is generally rugged and wild, framing a pattern of longitudinal and transverse valleys that are sometimes lush but invariably require irrigation to support agriculture. Parallel to this main range, about 2,500 miles in length, runs an interior range of less height and breadth. Rising west of the Darya-yi-Namak, a great salt lake south of Teheran, it leaves Isfahan to the west, bypasses the towns of Yazd and Kerman to the east, and then joins the main range in Persian Baluchistan around the extinct volcano Kuh-i-Bazman, 11,470 feet in height.

The other rugged arm of the V—the Elburz range—runs eastward parallel to the Russian border. Rising steeply from the Caspian plain, it breaks down in Khurasan into minor ranges extending to the Amu Darya and the Hindu Kush; but south of the Caspian Sea it rises to 12,140 and 15,592 feet respectively, in the Sahand and Sava-lan peaks of Azerbaijan, and to 18,600 feet in Mount Demavend, Iran's fabled and highest mountain, to the east of Teheran. To the east, along the Iran-Afghanistan border, a broken transverse range runs from north to south where the outstanding landmark on the Baluchistan border is the peak Kuh-i-Taftan, 13,261 feet high.

Deserts. Between these ranges, in the center of Iran, are the great deserts, between the Elburz range and Baluchistan: the Dasht-i-Kavir to the northwest and the Dasht-i-Lut to the southeast, separated by a series of oases. One of these oases, Tabas, is one of the most luxuriant creations of nature in all Iran. Part of its fame and the fame of Persian gardens in general is due to the contrast between the fertile land and the surrounding desert. The desert area of Iran, in which most of the country's interior drainage is lost, is one of the worst of Asia's wastelands, sustaining scarcely any life.

Coastal Regions. To the south and north of the mountain ranges forming the Iranian V are the Persian Gulf and Caspian coastal areas, so different in terrain and climate from the Iranian plateau. At the head of the Persian Gulf is the plain of Khuzistan, where the first Iranian kingdom of Elam arose and where the chief Iranian oilfields are located. Temperatures rise to 130° F, and high humidity adds to the discomfort. Similar climatic conditions characterize the narrow coastal plain of the Persian Gulf and Indian Ocean where only a few poor harbors can be found. In the north, on the Caspian littoral, which is below sea level, the climate is subtropical and the vegetation lush. The northern Elburz slopes are heavily wooded. Here the rainfall may exceed 60 inches a year, whereas on the high plateau, averaging 4,000 feet, the rainfall ranges from 6 to 7 inches in the center and south to as much as 35 inches in northwest Azerbaijan, the average being less than 12 inches. Most precipitation on the plateau falls between November and April. The moisture comes from the Mediterranean and Caspian seas, and descends usually as snow on the mountains, often remaining until midsummer. The water from melting snows moves to the plains and valleys in streams, on the surface and underground, to sustain crops and gardens. On the plateau the summers are clear and warm by day, the winters cold. In Teheran, located at an altitude of 3,800 feet, the temperature range is from 5° to 110° F.

Rivers. Roughly, the country has four drainage systems: Lake Urmia (Rizaiyeh) in Azerbaijan, the Caspian, the Persian Gulf, and the central desert. Short streams flow from both the Elburz and Zagros ranges into slowly shrinking Lake Urmia, which is about the size and salinity of the Great Salt Lake of Utah in the United States. The Aras (Araxes) River, which separates Persian Azerbaijan from Soviet Azerbaidzhan, flows into the Caspian Sea from the west. The Atrek and Gorgan rivers flow into the Caspian from the east, the former making a border for part of the way with the Turkmen Soviet republic. From the south, several small streams flow down the central Elburz into Mazanderan (the Chalus, the Haraz, and the Lar). To the west there is a large stream which, after rising on the western plateau as the Qizil Uzun and turning eastward, is joined by the Shah Rud, which drains the central Elburz behind Kazvin and Teheran; it then breaks through the mountain wall at Menjil and reaches the Caspian as the Sefid Rud, whose delta is the heart of Gilan province.

The largest river of Iran, the Karun, navigable for some 70 miles, is joined on the Khuzistan plain by the Ab-i-Diz and Karkheh. These drain the central western Zagros to the Shatt-al-Arab at the head of the Persian Gulf; the southeastern reaches of this range are drained by

small precipitous streams into the Persian Gulf. The inside slopes of the Zagros and Elburz ranges are drained by streams flowing to the central marshes and deserts, where much of their water, abundant during spring and early summer, is lost. Among these are the Jaj Rud, Karaj, and Kan near Teheran; the Qara Su near Hamadan; the Qum flowing near the shrine city of the same name; the Hableh east of Kashan; the Kur flowing past Persepolis; and the Zayendeh (Zaindeh) Rud, the largest of these, which waters Isfahan and its extensive plain. In 1953 the Zayendeh was enlarged by a tunnel connecting it with the headwaters of the Upper Karun. To the east, a part of the province of Seistan is fed by the Helmand, which flows into Helmand Lake (Hamun-i-Helmand) from the western Hindu Kush in Afghanistan. Its control has been a matter of dispute between Afghanistan and Iran.

Plants and Animals. Iran's variety of climate and rainfall causes uneven distribution of plant and animal life. In the central saline marshes and deserts there is less life than anywhere else in Asia, while on the subtropical Caspian littoral the forms of life are legion. On the northern Elburz slopes up to 6,000 feet are found the walnut, oak, maple, beech, ash, elm, cypress, cedar, honey locust, boxwood, and mimosa. On the plateau, the willow, walnut, tall poplar, mulberry, and plane tree are the most common. Seed-bearing plants—such as cotton, linseed, sesame, castor, and poppy—furnish oils. Wild plants and shrubs—such as gum arabic, tragacanth, asafetida, galbanum, colocynth, and licorice—produce valuable saps or resins. Vegetable dyes come from indigo, henna, saffron, and gallnuts. Many flowers are native to Iran—the tulip, rose, gladiolus, grape hyacinth, bellflower, gentian, poppy, geranium, crocus, primrose, violet, iris, pink, buttercup, cyclamen, hollyhock, jasmine, and honeysuckle.

In the Elburz forests there are tigers, leopards, wild boars, brown bears, stags, and lynx; foxes, panthers, wolves, jackals, and deer are widespread, as are porcupines, squirrels, hares, rats, and mice. Wild asses in the salt deserts, gazelles on the plains, wild sheep and goats on the mountains, and wild boars in swampy places attract hunters. Reptiles, turtles, lizards, and snakes abound, but only scorpions, tarantulas, and horned vipers of southern Iran are poisonous. Birds include the crow, raven, vulture, falcon, magpie, oriole, jay, sparrow, finch, lark, wagtail, warbler, thrush, robin, woodpecker, owl, heron, stork, quail, pheasant, partridge, pigeon, turtledove, duck, chicken, goose, and turkey. In the rivers of the Caspian littoral a variety of fish, such as sturgeon, salmon, carp, trout, and pike, flourish.

2. THE PEOPLE

Peasant village culture on the Iranian plateau goes back to Neolithic times, but the nature of the aboriginal stock is not clear. The indigenous inhabitants in the region of the Zagros Mountains were conquered around 1500 B.C. by the Aryans, who constitute the Indo-Iranian branch of the Indo-European-speaking family of peoples. Augmented by later Median and Persian incursions, they created a culture that has persisted for 3,000 years. To this group, besides the Persians, belong the Afghans, the Tajiks (Tadjiks), and the Kafirs of Kafirstan between the Hindu Kush and Kashmir.

Racial Stocks. The modern Iranian is racially the result of several thousand years of blending. The aboriginal groups mixed with the successive Aryan invaders and also with Central Asian peoples—the Parthians, Turks, and Mongols. In addition, the people of the Iranian plateau interbred to some extent with Westerners—the Aramaeans, Greeks, and Arabs. The purest types are probably to be found among the mountain tribes, such as the Kurds, the Lurs, and the Lakhs of Fars; among the endogamous Zoroastrians of Yezd and Kerman; and among the more isolated peasants less affected than townspeople by successive waves of invasion and conquest.

In Khuzistan, often called Arabistan, there are many Arabs, as there also are up and down the Persian Gulf coast. North of a line from Lake Urmia (Rizaiyeh) through Hamadan and Qum to the Russo-Afghanistan border, a large number of Turks are found, all speaking Turkish dialects, mostly Azeri (Azari). In the northeast, in Mazanderan, Gurgan, and parts of Khurasan, there are Mongoloid types, with high cheek bones, slant eyes, and sparse beards. The Baluchi of the southeast seem to be related to the old Dravidians of India. Among them are traces of Negroid characteristics, which has led some scholars to infer that the whole Makran coast of Baluchistan was once closely connected with East Africa through southern Arabia.

From 60,000 to 70,000 Armenians are found in Azerbaijan and Isfahan, and in the cities of Tabriz, Hamadan, Resht, Teheran, and Isfahan. The Nestorians, or Syriac-speaking "Assyrians," were once concentrated on the western shores of Lake Urmia. Reza Shah Pahlavi, who reigned from 1925 to 1941, took steps to consolidate them in cities in the north, particularly in Kermanshah, Hamadan, and Teheran. Despite considerable emigration to America, they probably number about 30,000 to 35,000 in Iran today. Some 40,000 Jews, the origins of whose community go back to Neo-Babylonian and Achaemenid times, live in the northern cities of Hamadan, Resht, and Teheran.

The Persian people today display a mixture of physical characteristics. Some are "Alpines," others have Mediterranean features and build, and still others have Mongoloid features. The people are usually medium in stature and slight of build, with dark hair and complexion, and brown or black eyes. Some of the women have fair complexions, with moon-shaped faces, delicate features, and large dark eyes sheltered by long lashes—the classic type of beauty in Persian romantic literature.

Nomadic Tribes. The tribes of Iran successfully resisted the efforts of Reza Shah to settle them on the land, although among them there have long been semisedentary elements. The tribes are virile, proud, and independent. They have often been the rulers of the land and have been accustomed to contribute their best warriors for its defense. They raise horses, cattle, and sheep, and perform an important economic function by producing meat, wool, hides, casings, and milk products from vast areas unfit for cultivation. Between them and the sedentary peoples there has always been a gulf of suspicion, if not of enmity—a clash of differing ways of life and patterns of values. One of the pressing problems of modern Iran is the fruitful integration of these long-neglected but strong and virile groups into the common life of the nation.

The largest and most distinctive of the tribes

Davis Pratt, Rapho-Guillumette

Mongoloid-featured Turkoman tribesmen hold a weekly bazaar 10 miles south of the Soviet Turkestan border.

are found in the Zagros Mountains. In the northwest part of the mountains are the Kurds, between Rizaiyeh and Kermanshah, numbering about 750,000. They are fiercely independent in their mountain fastnesses, where they have lived for at least 3,000 years. To the south of Kermanshah and Hamadan are the Lurs, related to the Kurds and, like them, residents of these mountains for several thousand years. Some 3,000 years ago the Kassites lived in this area. The beautiful Luristan bronzes are still being exhumed from their cemeteries. (See PERSIAN ART—*Bronze and Early Iron Age*.) Farther south, west of Isfahan and north of Shushtar, are the various branches of the Bakhtiari, a loose confederation related to the Lurs. Occupying some of the finest, most luxuriant, and picturesque mountain valleys of the whole country, nomadic branches of the tribe still trek long distances to pasture their stock in the highlands—a trek that was followed by Merian C. Cooper and his party in 1924, and dramatically recorded in the film and book entitled *Grass*. The Bakhtiari have often played a leading role in modern Persian history; the father of Mohammed Reza Shah's second wife, Soraya, was one of their chieftains.

The languages of these Zagros mountain tribes are Iranian, related to older forms of Persian. Farther south, in the mountains of Fars, are the Turkish-speaking Qashqai, many of whom migrate in the summer some 300 miles from around Firuzabad, south of Shiraz, northward to the borders of Isfahan province. Often allied to the Qashqai are the nearby Boir Ahmadi and Arab tribes, some of whom dominate parts of Khuzistan. In the southeast are the Baluchi tribes. In the Elburz Range in the north are to be found the various Turkoman tribes, who formed the basis of Safavid power in the 16th century. They are now largely absorbed into the sedentary life of the country, but some are still identifiable and active, such as the Shahsavan around Ardebil, the Zolfagari near Zenjan, and the Turkomans of Gurgan and Khurasan.

Language. The official language of Iran is Persian. Although it is written in Arabic char-

acters, it belongs to the Indo-European rather than the Hamito-Semitic family of languages. In its modern form it was reborn in Khurasan under the Samanids (874 A.D.-999), following the Arab conquest of 300 years before. So little has the language changed in the last 1,000 years that the epic *Shah Nameh* of Firdausi, written about 1000 A.D., is still understandable to the majority of the people, even though it is almost pure Persian as compared with the current speech, which has many Arabic words and phrases. Modern Persian can be traced back through Pahlavi, or Middle Persian, of the Parthian-Sassanid era to the Old Persian of the Achaemenids and to the Avestan of the Zoroastrian scriptures; and beyond these to Sanskrit, to which Old Persian and Avestan are closely related. Azeri Turkish is spoken widely over the northern half of the country, while in isolated valleys and separated provinces there are scores of vernacular dialects related to Persian at various stages of its development. See also IRAN, LANGUAGES OF.

Religion. Approximately 98 percent of all Iranians profess Islam, the official religion. Most of them belong to the Shi'ite sect, the minority branch of Islam. Kurds, Turkomans, and Arabs adhere to the majority branch of Islam, the Sunnite sect.

The Shi'ite branch of Islam is itself split into many sects. One of these is known as the Twelvers because they believe that the 12th imam (the 12th descendant of Mohammed beginning with his son-in-law Ali) is in hiding but will one day reappear as the Mahdi to usher in a period of universal Islam, peace, and prosperity. The Twelvers sect became Persia's official religion about 1500. The shah was considered the hidden imam's deputy and claimed descent from Ali. The crown continued to be closely associated with Islam until the secularizing reign of Reza Shah Pahlavi. Although there was a religious resurgence after 1941, the old Shi'ite fanaticism appeared to have lost its grip.

Sufism, the mystic form of Islam, was the philosophical religion of the Persian poets. Though long eclipsed and persecuted by Shi'ism, it has increased its influence, in a modernized form, especially among the educated and nationalistic youth.

Bahá'ism, another offshoot of Shi'ite Islam, was founded by Iranians in the 19th century. The Bahá'is and their predecessors, the followers of Mirza Ali Mohammed (known as the Báb), were severely persecuted by the Persian government. (See section 6. *History: The Kajar Dynasty and Foreign Influences.*) The influence of Bahá'ism within the country is less today than it was in the 19th century. The Bahá'is are not recognized by the law as forming a legitimate religious community.

Only about 20,000 Zoroastrians remain in the country as representatives of the classic religion of pre-Islamic Iran. Long persecuted and mostly confined to Yazd and Kerman, they are now honored by many who revere the nation's ancient traditions.

The Christian minority, numbering more than 100,000, consists mainly of Armenian Orthodox and Nestorians, with smaller numbers of Greek Orthodox, Roman Catholics, and Protestants. There are about 40,000 Jews. All these are recognized religious communities and are accorded religious freedom by law.

Marriage and the Status of Women. Though Islam permits polygamy, polygamy is on the wane in Iran, primarily because it is not economically feasible for most men to support more than one wife. Islam also allows temporary marriage, and divorce is relatively easy to obtain. Most marriages are arranged by the heads of families, since the family is still a powerful institution in Islamic society.

Women were protected to a degree in the past by the dowry, an institution that today is disappearing. But beginning with the legal reforms of 1925-1928, women's legal and political position

A village public bath near the Caspian Sea. Each village has a community bath, generally built by the local landowner.

Marion Wolcott, Pix

has greatly improved in other ways. In 1963 they were given the vote and allowed to run for office. With the discarding of the veil in 1935-1936, women also began to take advantage of opportunities for education and careers.

Conservative religious forces have been opposed, sometimes violently, to these changes in the status of women, and by and large the women themselves have been slow to avail themselves of the new freedoms. The great majority of them still marry young, preferring their traditional role to the "emancipated" role for women.

Dress, Food, and National Pastimes. Reza Shah's social reforms in the 1920's affected dress as well as other customs. In the 1920's the tarboosh (fez) worn by men gave way to the Pahlavi hat, a visored modification, which in the 1930's was replaced by the Western soft felt hat. In the cities, Western styles in clothing replaced the ancient Iranian style of dress. Following Reza Shah's abdication in 1941, many women returned to the veil. Village and tribal dress is still colorful and distinctive, although it too has been influenced by Western fashions.

The cuisine of Iran is deservedly famous, perhaps the best in western Asia. The diet of the peasant is frugal but on the whole balanced: bread, cheese, *mast* (thick soured milk), eggs, vegetables, raisins, nuts, dried fruits (fresh in season), and, on rare occasions, meat and fowl. A great variety of *dolmehs* or *dolmas* (vegetables stuffed with a mixture of meat, rice, and herbs), preserves, pickles, sauces, and stews adorn the tables of the middle and upper classes, along with pilaf (rice cooked with meat, vegetables, or spices). An endless variety of sweets are served. The national drink is tea, served in tiny glasses; it is the inevitable conclusion of a meal or accompaniment of conversation—business or pleasure. Hospitality is proverbial and calls for the best that one has, whether bread and cheese in the nomad's tent or the rich profusion of the landlord's or prince's table.

Both sexes smoke, generally cigarettes, although many still enjoy the old-fashioned *galyan*, or water pipe. Opium smoking, although now illegal, is still common, especially in certain sections of the south.

Conversation, including storytelling and versifying, and "taking the air" at sundown are favorite pastimes. Every village has its public bath and its teahouse where men gather to talk.

The *zurkhaneh*, or gymnastic center, flourishes throughout the country. Dating back to the remote past, it has in the 20th century been the training ground for the Iranian Olympic champions in wrestling and weightlifting. Iran is also the birthplace of the game of polo.

Picnicking is a universal custom. On Fridays, the weekly holiday, Iranian families often go to the country to picnic in shaded gardens. This becomes almost a national rite on the 13th day of the Muslim New Year, which brings to a close the national holiday festival at the time of the spring equinox.

3. ECONOMY

Once a great imperial power, Iran today is an agrarian and oil-producing country striving to enter the industrial age. Since World War II, it has built dams for power and irrigation and has established factories to process local raw materials so that the country would be less dependent on imports. It has improved and expanded its transportation network to facilitate the flow of goods within the country.

Nevertheless, industrialization in Iran is still in its infancy, and most Iranians continue to earn their living by farming, by herding, or in cottage industries such as rug making.

Agriculture. Though Iran is primarily an agricultural country, only about 11 percent of the land is arable. About 12 percent is forested, and 25 percent is in pasture and range. The rest is mountainous or desert, not suitable for cultivation. Of the 11 percent of arable land, one third is planted, while two thirds lie fallow.

The chief cereal crops are wheat, barley, Indian corn, and rice. These used to be grown in sufficient quantity to satisfy domestic needs, and there was sometimes a surplus of wheat and barley for export. Now wheat must be imported. Practically all the vegetables, fruits, melons, and nuts known in the West are cultivated in Iran. Fruits and nuts are among the most important agricultural crops for export. They include the famous melons of Isfahan, peaches and cherries of Meshed, grapes of Shiraz, apricots of Hamadan, pistachios of Kerman, and almonds of Azerbaijan. Citrus fruits abound along the Caspian. Dates are grown in the oil province of Khuzistan and in the warmer regions on the Persian Gulf.

Cotton is Iran's principal cash crop. It is grown in the Caspian Sea provinces, which also

A tobacco crop is cured in a village near the Caspian Sea. This variety is used in making Turkish tobacco for cigarettes.

Davis Pratt, Rapho-Guillumette

Iran: Principal cities, products, and resources.

produce tobacco, tea, and raw silk. Sugarcane and sugar beets are raised, but not in large enough quantities to meet domestic needs. Cultivation of the poppy has been prohibited since the suppression of the opium trade in 1955.

Irrigation is necessary throughout most of Iran. Only the lush Caspian plains and the dry-farming regions of Azerbaijan and Khurasan have adequate water without irrigation. Near the streams and rivers, water can be brought across the land surface to the croplands. In other areas it is necessary to use long and expensive underground channels or aqueducts, which tap the seepage from the mountains and bear it to fertile soil. This method probably dates back to prehistoric times.

The building of dams for irrigation and power has been given high priority in the government's post-World War II development plans. The Karaj Dam, west of Teheran, begun in 1958 and completed in 1961, irrigates the farmland south of the capital. The Sefid Rud has been dammed to irrigate 600,000 acres, and the Dez Dam in Khuzistan, built to restore the province's position as an important grain-producing area, was dedicated in 1963.

Land Reform. Until after World War II, about 80 percent of the land and the villages was owned by absentee landlords, religious groups, and

the crown, or was in the public domain. In 1950 the shah began distributing crown lands to peasants, who were to pay for the land over a 25-year period. In 1958 the government began distributing the 10 million acres of public land. When the large landowners failed to follow suit, the government decreed in 1962 that each landowner owning several villages must give up all but one. He was required to sell the rest to the state for resale to the peasants, who could pay for the land over a 15-year period. Two years later, landlords with small holdings of one village or less were required to give up some of their land, retaining a maximum of 75 acres to 370 acres, depending on the region. The state outlawed sharecropping and required landlords to pay money wages to their farmers.

Distribution of the holdings of the large landowners proved less troublesome than the breaking up of the holdings of the approximately 100,000 landlords owning one village or smaller tracts. These small landlords, who owned over half of Iran's agricultural land, faced economic ruin because the land reform law eliminated the source of much of their income.

A second problem that faced the reformers was how to instruct the illiterate peasantry in modern farming and marketing techniques. To meet the problem, the government established farm co-

operatives. But the country had almost no experience with cooperatives, especially for credit and marketing, and there was a shortage of skilled personnel who could give advice on such matters as scientific land use, irrigation methods, soil improvement, the handling of modern equipment, use of pesticides, and other phases of scientific farming. It became increasingly apparent that the redistribution of the land was only the first, and in some ways the easiest, stage in the agricultural revolution.

Herding, Fishing, and Forestry. The nomadic tribes of Iran raise sheep, cattle, horses, goats, asses, and camels. Though herding is done on an extensive scale, meat is relatively expensive. It is a rare luxury for most, who depend upon milk products, eggs, and nuts for proteins.

Fishing is a minor industry, carried on mostly with primitive equipment. The caviar industry is important, however. Iran is the world's chief supplier of caviar, taken from the Caspian Sea sturgeon.

There are valuable forests along the northern slopes of the Elburz mountain range, which rises from the southern coast of the Caspian Sea. The rest of the country has been almost denuded of trees by nomads and peasants using the wood for fuel, and by animals grazing on the new shoots. Reforestation was begun in 1956, and in 1963 nationalization of the forests was approved in a national referendum.

Petroleum and Other Minerals. Iran earns more foreign currency from the sale of crude and refined oil than from any other item of export. The total production of oil in the country has risen steadily since the first well went into production in 1908. Oil production increased from 237,807,500 barrels in 1950 to 605,844,646 barrels in 1964. Iran ranks sixth among the world's producers of oil, stands fourth in the world as an oil exporter, and accounts for about 10 percent of the world's oil reserves.

The major oilfields are located in the province of Khuzistan at the head of the Persian

Gulf. These fields are connected by pipelines to the large refinery on Abadan Island in the Shatt al-Arab delta. Abadan refines only about 25 percent of the oil produced. The remainder is shipped as crude oil to consumer countries—such as Britain and Australia—that have more refineries than Iran.

The petroleum industry was nationalized in 1951. When the government found it impossible to produce and market oil without foreign technical aid and international marketing cooperation, the government-owned National Iranian Oil Company (NIOC) and a consortium of foreign companies signed an agreement in 1954, under which the foreign companies were to operate the oilfields in the original concession area for 25 years. (See section 6. *History*: Nationalization of the Petroleum Industry.) Subsidiary companies were formed to market the oil.

Foreign companies and the NIOC as partners operate the offshore fields in the Persian Gulf. The NIOC controls the oil industry in all other parts of the country. It operates fields near the Iraq border in Luristan province and at Qum, 75 miles southwest of Teheran. The Qum strike was made in 1956, and the field went into operation in 1961. But these fields produce only a very small amount compared with the petroleum yields in Khuzistan.

Iran has substantial reserves of natural gas, but most of this resource has in the past been flared at the oilfields rather than used as a source of power.

Iran mines some coal, iron, chrome, and lead. There are small deposits of other minerals, but these have not been adequately surveyed. Building materials—such as stone, limestone, and gypsum—are widely quarried, and marbles and alabaster are available. Near Nishapur, fine turquoises have been mined for centuries.

Manufacturing. The industrialization of Iran, which dates from World War I, has developed primarily in and around Teheran. The capital has factories for the manufacture of matches, cement, shoes, jute, munitions, furniture, building materials, and plastic and rubber products. Vegetable-oil and soap factories and tobacco-processing plants are also located at Teheran. Only a few of these employ more than 500 workers.

The textile factories of Iran, which produce woolen, cotton, and silk cloth, are largely centered in Isfahan and Mazanderan. There are fish and caviar canneries on the Caspian Sea and Persian Gulf coasts, and vegetable and fruit canneries in the northern part of the country. Several large sugar refineries operate in the central plateau region. A dozen cities have rug factories with hand-operated looms. Many of the country's rugs are woven in the winter by the peasants.

Labor. Prior to industrialization, all labor was organized in crafts and guilds. For many local products this system still prevails.

Labor unions first became legal in Iran during World War II. In 1942 the Tudeh party—later revealed as Communist-controlled—sponsored the Central Committee of Trade Unions, which organized local unions in industrial centers. By political pressure and strikes, the unions succeeded in improving working conditions for the fast-growing number of industrial workers.

In 1946 the ministry of labor issued regulations for labor unions and managed to absorb some of the unions into the government-sponsored

Sturgeon, taken from the Caspian Sea, is opened, and caviar, its precious roe, is carefully removed.

Dalmas, Pix

World Bank

The Dez Dam was built in 1963 to provide enough water for irrigation to restore Khuzistan as a great grain center.

Union of Iranian Workers. Thereafter the government intervened on several occasions to compel management to satisfy labor's demands. In 1961 the government announced that factory owners would be required to build homes for their workers. Two years later, in order to provide incentives for greater productivity, the government decreed that contracts should be drawn up by labor and management permitting the workers to share in the company's profits. At the same time the right of collective bargaining was affirmed. However, this imposing series of labor laws was only rarely enforced in the succeeding years.

Power. The power needs of Iran's industries have greatly exceeded the amount of power available. To help overcome the shortage in Teheran, where about half of the country's industrial plants are situated, an oil refinery and natural gas complex were developed in the 1960's at Qum, a town near the capital. In order to increase the output of hydroelectric power, the government made the construction of large multipurpose dams a major goal of Iran's post-World War II development programs.

Foreign Trade. Iran's economy has suffered consistently from an unfavorable balance of trade. The chief exports are crude and refined petroleum and petroleum products, which account for about two thirds of the value of the country's exports. Other exports are raw cotton, carpets, and dried fruits and nuts. Iran has continued to depend on more industrialized countries for machinery, manufactured goods, industrial raw materials, and chemicals and pharmaceuticals. It also imports staple foodstuffs, such as sugar, to make up for deficiencies in its own agricultural output.

West Germany, the United States, and Britain have been important to Iran as both suppliers and purchasers. The Soviet Union provides another market for Iranian goods. In the 1960's Iran began to import goods from Japan.

Transportation. Because the lack of good roads seriously hampered the economic development of the country, road building was given a high priority in the postwar development plans. By the 1960's, however, less than one fifth of the

roads in Iran were asphalted. Very few of them were suitable for heavy trucking, and Iran had difficulty in maintaining the roads over the country's rugged terrain.

The country was first traversed by rail in 1938 when the city of Bandar Shah, situated on the Caspian shore near the boundary with the Soviet Union, was connected with the Persian Gulf ports. This difficult engineering feat took 10 years to complete. East-west extensions of the line were begun shortly before World War II. By 1957 the railroad had reached the Soviet border north of Tabriz. In the following years construction proceeded on a railroad link between Tabriz and Turkey, a project that was sponsored by the Central Treaty Organization (CENTO), to which both Iran and Turkey belong. A line was also constructed from Teheran to Meshed in the northeast and one was projected to West Pakistan through Yazd, Kerman, and Zahidan.

The island of Abadan is the chief port for the shipment of refined oil and petroleum products. Crude oil is shipped from Bandar Mashur and also from Kharg Island, to which the oil is pumped through a 25-mile underwater pipeline. Other goods are shipped out of the country primarily through the port of Khorramshahr on the Karun River at the head of the Persian Gulf. Other Persian Gulf ports are Bandar Shahpur, Bushire, and Bandar Abbas across from Oman. Trade with the USSR is through the Caspian ports of Pahlavi, Chalus, and Bandar Shah.

Most foreign passenger travel and mail is by air. Internal air traffic is a monopoly of the Iranian National Airlines, which is 50 percent government owned.

Currency. The treasury issues the rial as the standard monetary unit. Silver coins of 1, 2, 5, and 10 rials are minted, and there are bronze coins of 50 dinars (100 dinars = 1 rial). The monetary system provides for gold coins of one pahlavi and one-half pahlavi, but these are not in circulation. Bank notes range from 10-rial notes to 1,000-rial notes. Par value of the rial in 1965 was 75.75 to the U.S. dollar.

The monetary and banking law of 1960 required that at least 40 percent of the total note issue must be backed by gold and foreign currencies. Although their monetary value is incalculable, the royal jewels and treasures on deposit in the National Bank in Teheran are of psychological value in backing the currency.

4. EDUCATION AND MASS COMMUNICATIONS

Iran's entry into the industrial age has been hampered by a low degree of literacy. Only about 15 percent of the population can read. As one might expect, the rate is much higher in Teheran and the other large cities, while it is much below the national average in the peasant villages and among the tribes. In order to meet the problem of illiteracy, a law was enacted in 1943 making elementary education (through grade six) compulsory and free for all, both boys and girls. The law, however, is still an ideal rather than a fact, since the number of teachers has been wholly inadequate for this vast job and there have not been sufficient funds to construct the necessary schools. Illiteracy among the nomadic tribes has proved to be the most difficult to eradicate. It has remained virtually untouched by the law, although efforts to teach them to read are being made through itinerant teachers who move with the tribes.

Chapelle, Monkmeyer

A shortage of teachers and the remoteness of many Iranian villages have hampered efforts to raise the literacy rate.

Schools. By the mid-1960's approximately 50 percent of elementary school-age children were in school. This percentage represents a great improvement over the 1950's. Whereas in 1950 there were about 2,000 elementary schools with 264,000 pupils and 8,000 teachers, in 10 years these numbers had increased fivefold. In order to accomplish this advance in education, the number of teachers colleges was increased from the 25 opened by 1934 to 66 in 1960. The itinerant school system for the tribes was inaugurated in 1955, and 7 teachers colleges were established to train teachers for them.

Secondary schooling is neither compulsory nor free, and relatively few go on to these grades. In 1950 there were 455 secondary schools with about 27,000 pupils; by 1960 the number of schools had doubled. However, the number of secondary school teachers jumped from 1,700 in 1950 to 11,000 in 1960, and the number of students rose to 280,000. During this period, the stress was shifted in the secondary schools from college preparatory work to vocational training. The change in goals was paralleled by an increase of technical schools, which rose to about 70.

A beginning was made in developing literacy among adults by establishing evening classes and part-time day schools, especially in rural areas. Literacy programs were also instituted by the armed forces. At the same time, the shah's 1963 education program instituted a "literacy corps" of high school graduates exempted from military service. Members of the literacy corps are assigned to villages to teach village children to read and write. Though improvements were discernible, the goal of compulsory primary school education for all was far from being realized. It proved difficult to attract the required number of people to the teaching profession because of low pay. Teachers were so poorly paid that they had to resort to strikes to gain even a living wage.

The government established the University of Teheran in 1934. Its student body of 15,000 is divided among the faculties of arts, education, agriculture, fine arts, science, technology, medicine, dentistry, pharmacy, veterinary medicine, and

law. There are also universities in Tabriz, Shiraz, Meshed, and Isfahan. For the most part, the professors have been trained in Europe and in the United States.

Press, Radio, and Television. Iran has numerous daily and weekly papers or magazines, most of them published in Teheran. Ettelaat, the country's largest publishing company, brings out dailies in Persian, French, and English, an overseas newspaper in Persian, a weekly magazine, and a monthly journal. Almost equal in importance to Ettelaat is Kayhan, with a daily in Persian and English, and an English weekly for the Middle East. Many of the other dailies are personal political sheets or organs of pressure groups. The chief provincial cities also have dailies, but their sales are small.

Newspapers are frequently suspended when the government objects to their editorial policy. A technical suspension of only a few hours has generally been sufficient to bring a newspaper's point of view at least temporarily in line with the government's.

Radio Iran, which was founded in 1938, is government owned and operated. It broadcasts from Teheran not only in Persian, but in Urdu, Kurdish, Arabic, Turkish, English, Russian, and French. There are also radio stations in the other chief cities. In 1963 there were close to a million radio receivers. The television stations are privately owned. Their programs were received on approximately 67,000 sets in 1962.

5. GOVERNMENT

Iran's form of government was established by the constitution of 1906 and its subsequent amendments. The constitution provides for a monarchy, an executive branch composed of a premier and cabinet, and a parliament composed of an upper house, the Senate, and a lower house, the Majlis.

Iran is not a full-fledged parliamentary monarchy. The shah has at times ruled autocratically, forbidding the formation of political parties, or creating parties that would not balk his wishes, and then allowing only these parties to contest an election. Parliament was suspended altogether in 1961 when it threatened to block the shah's

program. However, the constitution has survived severe political crises, and it remains a blueprint for the government of the nation, at least in times of relative tranquility.

Executive. By the terms of the constitution, the shah has command of the armed forces; he has the sole authority to declare war and conclude peace; and he names and dismisses the premier, although his choice must be confirmed by the lower house, the Majlis, to which the premier and cabinet are responsible for executive action. Parliament may be dissolved by the shah.

Legislature. Half of the Senate's 60 members are appointed by the shah, and half are elected indirectly by the people.

The lower and more powerful house, the Majlis, has 200 members, elected every four years. Election was by universal male suffrage until 1963, when women over 18 were given the vote.

Members of the legislature must be Muslims except for four members in the Majlis: the Christians are represented by two members, the Jews and Zoroastrians by one each. To become a law, a bill must be approved by both houses unless it is a bill pertaining to public finance. In that case it needs the approval only of the Majlis.

Political Parties. Under Reza Shah (reigned 1925–1941), all political party activity was proscribed. After his abdication in 1941, the Tudeh party, which was Communist-oriented, was formed. It played an important role in national politics until it was outlawed in 1949 after an attempt on Mohammed Reza Shah's life had been traced to the Communists. Driven underground, the Tudeh continued to work through other political groups set up as fronts for it.

Mohammed Mossadegh's party, the National Front, achieved considerable power during Mossadegh's premiership (1951–1953), then went into decline with his removal from office. The two parties created by the shah in 1957–1958—the Mardom and the Milliyyun—were too artificial to survive. They were not revived in the 1963 election. Instead, a new government-sponsored party, the New Iran party, presented a slate of candidates to the electorate. No other party was allowed to participate in the election, although some candidates without party affiliation ran for office. See also section 6. *History*: Recurrent Economic and Political Crises.

Judiciary. Iran's courts are modeled after those of France. The Supreme Court is the court of final appeal but does not have the power to decide the constitutionality of legislation. Judges try all cases except a few for which juries are called. Judgments are based on the codes enacted under Reza Shah to replace the Islamic religious law.

Local Government. For political and administrative purposes, Iran is divided into 13 *ostans* or provinces—or 14, if the island of Bahrain, to which Iran lays claim, is included. There are also 6 general governorships. Within the *ostans* are subprovinces called *shahristans*, which are made up of *bakhshs*, or counties; within each *bakhsh* are several *dehestans*, or districts, which in turn comprise several villages.

The governors of the *ostans* are appointed by the central government and are responsible to it. In this way the central government has tried to prevent the resurgence of the kind of local autonomy that enabled the USSR to establish the states of Azerbaijan and Kurdistan in 1945 (see section 6. *History*: The Cold War).

6. HISTORY

In prehistoric times there was a great movement of tribes south and west from the steppe country north of the Caspian Sea. These were the Aryans, who settled first in Iran and then dispersed, some south into India, and some west as far as the Zagros Mountains. Assyrian, Hittite, and Egyptian records of about 1500 B.C. disclose Iranian names and portraits. As early as 1700 B.C. the horse, known from remote times to the Aryans, seems to have been introduced to the Greeks and Egyptians by Iranian mercenaries. Numerous Aryan tribes, speaking for the most part some form of ancient Persian, gradually settled most of the Iranian plateau. They also settled what is now southwestern Iran, which was the ancient kingdom of Elam. The Medes, people of another Aryan strain, occupied the high mountainous plateau in northwestern Iran and appear in history about 836 B.C.

The Achaemenids. The first Persian empire was created in the 6th century B.C. by the Achaemenid dynasty. The dynasty took its name from its founder, Achaemenes (Hakhamanish), who in the 7th century B.C. ruled Parsumash, a small kingdom northeast of Elam. Achaemenes and his son Teispes were subdued by the Medes. Nevertheless, in alliance with Assyria, they were able to take over what is now the Iranian province of Fars. One of their successors, Cambyses I (reigned 600–559 B.C.), married the daughter of the Median king Astyages, and their son Cyrus II the Great came to the throne of Fars in 559 B.C.

Cyrus immediately revolted against Media and defeated Astyages in 550 B.C. In 546 he overthrew Croesus of Lydia, and in 539 he took Babylon. The fall of Sardis in 546 B.C. and the ensuing capitulation of the Greek towns brought the Persians to the Mediterranean. Meanwhile, the nomads to the east and the tribespeople of the plateau had been drawn into the rapidly consolidating Persian empire. In 529 B.C., while campaigning against the eastern border nomads, Cyrus was killed.

Cyrus' son Cambyses II (reigned 529–522 B.C.) fulfilled his father's plan to conquer Egypt, the last great power to fall to the Persians. Upon receiving reports that Gaumata the Magian had usurped the throne in Persia, however, Cambyses, en route from Egypt, committed suicide.

Gaumata's uprising was unsuccessful, and Darius I, who belonged to another branch of the Achaemenid family, became king in 522 B.C. Under Darius the empire reached its greatest territorial extent. After subduing revolts in half a dozen provinces, Darius crossed the Bosphorus, successfully engaged the Scythian tribes along the Danube, and pacified Thrace and Macedonia. He then turned to India and penetrated well into the Punjab and Sind. In 499 B.C. the Ionians and the Carians, aided by Athens and Eretria, rebelled. This action precipitated a long series of disastrous campaigns against Greece, the most famous of which ended at Marathon (490 B.C.).

Darius was succeeded in 486 B.C. by his son Xerxes, who continued the Persian wars against the Greeks. But his fleet was cut to pieces by the Athenians at Salamis in 480 B.C., and his magnificent infantry fell before the Greek phalanx at Plataea the following year. The Achaemenid rulers never again attempted any serious campaign of territorial expansion.

The imperial organization begun by Cyrus and

The ruins of the imperial palace at Persepolis recall the greatness of the Persian empire under Darius I and Xerxes.

perfected under Darius I was wisely conceived. The military superiority of the Persians was due largely to their lightly armed bowmen, unsurpassed in courage and skill, and to their distinguished cavalry. Although imperialistic wars were waged, at no time in history have conquered peoples been more honorably and generously dealt with in matters of administration, law, culture, or religion. The Persian leaders worshiped "the great God, Ahuramazda," but there was no attempt to enforce his worship on others.

During the hundred years following the Greek wars the empire slowly disintegrated. Rebellions, intrigue, and assassinations, combined with degeneration of the royal line, brought the glorious Achaemenids to an ignoble end.

Alexander and the Seleucids. Under Darius III (reigned 336–330 B.C.), last of the Achaemenids, the empire was lost to the Macedonian ruler, Alexander the Great. The Persian capital, Persepolis, was burned, Darius was murdered, and Persia became a part of the Macedonian empire. Alexander died in Babylon in 323 B.C., and his empire was divided among his lieutenants. Seleucus I Nicator (assassinated 280 B.C.) acquired by conquest and intrigue the greater portion of Alexander's Asian domains, with Persia at its core. (See **SELEUCIDS**.) Border warfare and internal troubles followed, and gradually the Persian kingdom fell prey to the neighboring Parthians.

Parthian Rule. The Parthians were an Iranian people who had successfully established an independent kingdom to the northeast in what is modern Khurasan. (See **PARTHIA**.) By 138 B.C. they had expanded their rule to cover almost exactly the territory of modern Iran. The Ar-

sacid dynasty of the Parthians claimed descent from the Persian king Artaxerxes II, and they worshiped the god Ahuramazda. But their culture was Philhellenic. (See **ARSACIDS**.) They had a long history of opposition to Rome. Orodes II (reigned 57–37 B.C.) defeated Marcus Licinius Crassus in 53 B.C., and in 36 B.C. Phraates IV (reigned about 38–2 B.C.) overcame Mark Antony. The last Parthian king, Artabanus V (reigned about 213–224 A.D.), won a decisive victory over the Romans in 217 A.D.

Sassanids. About 224 A.D. Ardashir, a ruler of one of the small states within the empire, who claimed descent from the Achaemenid line, revolted against his Parthian overlord and defeated him on the plains of Hormuz. He established the line of Sassanid kings who were to rule Persia for more than 400 years, until the Arab conquest in 641.

The Sassanid period was characterized by a revival of the ancient Achaemenid culture and a corresponding lessening of Greek influence. Ardashir restored the Zoroastrian religion, collected its sacred texts, and reinstated the priestly Magians. He defeated the Roman emperor Alexander Severus in 232 A.D., but he did not push his advantage or retain Mesopotamia in the subsequent peace because his interest had shifted to the east, where he extended his borders. Shapur I (reigned 241–272 A.D.), son of Ardashir, captured the Roman emperor Valerian in 259, but, it was left to Shapur II the Great (reigned 309–379) to secure the western frontiers finally against the Romans.

During the reign of Bahram I (reigned 273–276), successor to Shapur I, the new Manichaean religion gained a considerable following at the

Persian court. But the Magian priests intrigued against the religion's founder, Mani. In 276, Mani was executed, and the Manichaeans were driven from court.

Royal intrigue, religious strife, internal trouble, and border warfare characterized the century after the death of Shapur II in 379 until the accession of Kavadh I (Kobad; reigned 488-498, 501-531). Kavadh restored internal order and crushed the White Huns from inner Mongolia, who had long harassed the eastern outposts of Persia.

In the same century there was a constantly changing official policy toward Christians and Jews. But in 483, under Firuz II (Peroz; reigned 457-484), the Nestorian doctrine was recognized as the legal form of Christianity in the Persian empire.

Khosrau I Anushirvan (reigned 531-579), also known as Chosroes I and as Noshirwan, was the most illustrious of the Sassanid rulers. He was successful against both the Romans and the newly powerful Turks, and he aided the Yemen Arabs in expelling the Abyssinian invaders. Internally, Khosrau completely wiped out the Mazdakites, a communistic sect that had flourished under his father, and he restored Zoroastrianism. He revised the tax system, made great advances in administration, and generally proved himself an enlightened monarch. After his death, dissension and rivalry enfeebled the kingdom.

In the 630's Islam began its sweep over the Middle East and North Africa. In 641 at Nehavend, south of modern Hamadan, the Sassanid ruler Yazdegerd III was routed by the Arab Muslims. Ten years later he was murdered at Merv, and the Sassanid dynasty came to an end.

Caliphal Rule. By 650, with the exception of a few remote and isolated districts in northern Media, the Arabs had reached the Oxus River (modern Amu Darya), and Persia had become a part of the caliphal empire. Arab administration was reasonable, and there was little interference with folk customs or religion as long as order was maintained and taxes were paid. Many Persians became Muslims under economic pressures. In 750 the Umayyad (Omayyad) caliphate was supplanted by the Abbasids, who moved their capital to Baghdad in 762. Thereafter the Persians gradually rose to a position of increasing importance intellectually, socially, and politically in the Islamic empire.

With the gradual disintegration of the Abbasid caliphate, numerous minor dynasties succeeded one another in Persia. Among these, the Samanids (874-999), who had first been governors in Turkestan and Khurasan, gradually built up a strong feudal kingdom, genuinely Persian in culture. Its enlightened rulers revived the Persian language, were patrons of art and learning, and expanded commerce.

The Abbasid caliphate had imported Seljuk Turks and other mercenaries. Eventually, under a merely nominal sovereignty of the caliphs, the Seljuks gradually assumed power and control. (See SELJUKS.) Most famous of these Seljuks was Malik Shah (Jalāl-al-Dīn Malikshāh, reigned 1072-1092), with whom the power of the Seljuks reached its zenith. Illustrious Persian intellectuals flourished in this Seljuk period: Firdausi (940?-1020), creator of the Persian epic, the *Shah Namah*; Avicenna (980-1037), physician and philosopher; 'al-Ghazzālī (1058-1111), philosopher and theologian; and Omar Khayyām (d. about

1123), who was a poet-philosopher, mathematician, and astronomer.

Mongol Rule. In 1220 the invasion of the Mongols began, first under Genghis Khan and then under his grandson Hulagu Khan, who took Baghdad in 1258, bringing the caliphate to an end. Hulagu became the first Il-khan (provincial ruler). He and his successors controlled Persia until the middle of the 15th century. The Mongol Tamerlane (Timur; about 1336-1405) ravaged, pillaged, and destroyed everything before him, but his son Shah Rukh (reigned 1404-1447) repaired much of the devastation and encouraged a revival of art and science.

Safavids. In 1502 a new national dynasty, the Safavids (Safawids; 1502-1736), arose and put an end to foreign domination. Through their ancestor, Safi-al-Din, the Safavids traced their line to the seventh imam and through him to Ali, the son-in-law of Mohammed. They, therefore, made Shi'ite Islam the official religion of Persia. Shah Ismail I (Ismā'il; reigned 1502-1524) defeated the Uzbeks in the northeast, while on the west he reorganized Azerbaijan against the Ottoman Turks, now the strongest enemies of the Persians. Shah Abbas I the Great (reigned 1587-1629), in a series of wars, routed the Ottomans and regained all the territory formerly lost by Persia, including Baghdad. Abbas was not only a great military leader. His fame also rests on his religious tolerance, his genius for organization and administration, and his patronage of architecture and science. He rebuilt Isfahan and made it his capital, established profitable commerce with Europe, and welcomed travelers and ambassadors. During his reign the British and Dutch wrested the Persian Gulf from the Portuguese. But Abbas' jealousy of his sons prevented the training of an heir to carry on his splendid work, and the century following his death in 1629 was a period of slow decline.

Under Abbas II (reigned 1642-1667) there was a brief revival of Persia's glory, but by 1722 Isfahan had fallen to the rebelling Afghans, and

This bull's head once adorned the palace at Persepolis.

Hossein Sangui

Shah Abbas, the great Safavid ruler, moved the capital to Isfahan in 1598 and embellished it with this ornate mosque.

during the ensuing chaos Russia and Turkey seized large parts of Iran. Nadir Kuli Beg, an Afshar tribesman and brigand, joined by Prince Tahmasp, collected a large force and routed the Afghans, regaining much territory in Khurasan. Successful military raids and campaigns also led to the expulsion of the Russians and the Turks. In 1736, after deposing the last Safavid ruler, Nadir was crowned shah. He then attacked India, sacking Delhi, and conquered Khwarizm (Khiva) and Bukhara. Unfortunately, he had little administrative ability, could not stand success, grew arbitrary and despotic, and appeared at times derailed. He was murdered in 1747.

The Kajar Dynasty and Foreign Influences. The Kajar and Zand tribes contested for the throne, and Karim Khan, a Zand of Fars, was victorious. He retained the designation *vakil* (regent), never assuming the royal title of shah. From 1750 to 1779 he reigned justly and humanely, and has become a legend in Iran. He moved the capital to Shiraz, and enlarged and beautified the city. Agha Mohammed Khan, of the Kajar tribe, who proved to be a cruel ruler, became the first of the Kajar kings, who were to rule until 1925.

Beginning with the reign of Fath Ali Shah (reigned 1797–1834), Persia rapidly became drawn into European power politics. Napoleon, with an eye to attacking the British in India, concluded a treaty with Persia in 1807 and sent a military mission to Persia to train an army. Two months later, however, Napoleon made a treaty with the Russians at Tilsit, and the shah could hope for no help from France in regaining Georgia from Russia. In 1814, Persia concluded a treaty with Britain whereby in effect Persia became a buffer state between India and Russia. Military campaigns in Georgia ended in complete disaster for the Persians, and in 1828 the Russians forced on them the Treaty of Turkmanchai, by which Persia lost most of her territory in the Caucasus to Russia. Russia also demanded extra-territorial rights within Persia and an indemnity. This treaty set the example for the conduct of other European nations in their later negotiations with Persia.

In 1834, Britain and Russia guaranteed Persian independence. Mohammed Shah (reigned 1834–1848) attempted to regain prestige by the conquest of Afghanistan, but Britain, fearful of Russia's dominance of Persia in Afghanistan, succeeded in bringing about his withdrawal.

Reign of Nasr-al-Din. Mohammed Shah's death left his son Nasr-al-Din heir to a government on the edge of bankruptcy and revolution. Nasr-al-Din reigned from 1848 to 1896. During this long period Persia became more and more involved with foreign interests, to which it was forced to make more and more concessions. To protect their position in India, the British wanted to build a strong Afghanistan as a buffer to the advancing imperial aims of Russia. By the brief Anglo-Persian war of 1856, the British compelled Persia to evacuate Afghanistan completely in 1857. By 1864 the British had constructed telegraph lines to India through Persia, and in 1889 they obtained a favorable concession in the founding of the Imperial Bank of Persia. The British also opened the Karun River to navigation and commerce.

Meanwhile various military missions succeeded one another in Persia—British, French, and Austrian—but the Persian Cossack brigade, Russian-trained and officered, was the only efficient and reliable unit.

Nasr-al-Din had begun his reign auspiciously by appointing Mirza Taqi Khan of Tabriz as his vizier. Taqi Khan was brilliant, industrious, and devoted. The much-needed reforms he instituted produced a swarm of enemies who brought about his execution—a tragic disaster for Persia. The shah was not opposed to reform, and his three visits to Europe had awakened his interest in enlightened rule, but he was unqualified for effecting modernization and was hampered by jealous foreign interests that constantly interfered with or blocked many of his attempts. He did, however, establish the beginnings of a modern college in Teheran and sent many young Iranians to France for higher education. The ruthless persecution of the Bábist sect (later Bahá'í), a religious group founded in Shiraz by Mirza Ali Mohammed, the Báb, was a blot on his record. See BĀBISM.

The End of the Kajar Dynasty. Under Muza'far-al-Din (reigned 1896–1907), the British and Russians again played off one another to Persia's loss, with Russian influence on the increase. A British loan in 1892 was countered by a Russian one in 1900, guaranteed by customs receipts, except those from Persian Gulf ports. The terms of the Russian loan stipulated the payment of the British loan, and prohibited the obtaining of any further foreign loans within 10 years. But the Russian loan was dissipated by the shah's personal extravagances, and Mohammed Ali Shah, succeeding in 1907, took over a bankrupt government.

During the reign of Nasr-al-Din, a movement had begun to limit the shah's power. During Muza'far-al-Din's 10-year reign, there was a marked deterioration in respect for the throne. By 1905 there was a definite movement in favor of a constitution, and a dramatic series of events brought about the formation of a National Assembly which Muza'far-al-Din opened just before his death. The next shah, Mohammed Ali, supported by Russian influence, attempted three times to overthrow the constitution, but he failed and was forced to abdicate in 1909 in favor of the boy king, Ahmed Shah, the last Kajar ruler.

Meanwhile, Russia was ready to conclude an agreement in Asia with Britain to prevent the spread of German influence. By the Anglo-Russian Convention of 1907, Persia was to be divided into two spheres of economic influence, the Russians to control the entire north as far south as Isfahan and Yezd, and the British to take over

the southeast, with a neutral zone separating them. The convention was soon rendered strategically obsolete from Britain's point of view by the discovery of oil in Persia. In 1901 a concession had been granted to William Knox D'Arcy, a British subject, establishing a monopoly in the search for and exploitation of oil in Persia, with the exception of the five northern provinces. In 1909 the Anglo-Persian Oil Company was formed, based on this monopoly. In 1914, following the conversion of the Royal Navy from coal to oil for fuel, the British government became the majority stockholder in this company.

In May 1911, William Morgan Shuster, a United States citizen, was brought to Persia as financial adviser, to build a fiscal foundation for constitutional independence. As treasurer-general, Shuster won the approval of the liberal forces in the country by his skill in reorganizing the country's finances. Alarmed by Shuster's success, which bolstered liberal forces, Russia demanded his dismissal and threatened to occupy Teheran. Russian bribery and intrigue, together with a show of military force, brought about the illegal dissolution of the National Assembly, or Majlis, in December 1911 and the termination of Shuster's contract. Belgians were then brought in as customs administrators, but no real general improvement was possible.

Russian influence continued to increase until World War I when Persia, unable to defend her declared neutrality, became a cockpit of intrigue and fighting between the Allies and the Central Powers. At the Paris Peace Conference in 1919, Persia submitted claims for the return of her territory annexed much earlier by Russia and Turkey, cancellation of special privileges accorded to certain foreigners, and reparations for damages caused by the war. She was not allowed to plead her case. Subsequently Persian pride was appeased by an invitation to become a charter member of the League of Nations.

Under an Anglo-Persian agreement in 1919, Britain guaranteed the independence and integrity of Persia, agreed to supply advisers to reconstruct the administration, and also agreed to reorganize, staff, and equip the Persian army. Persia was to receive a loan, guaranteed by customs receipts. Anglo-Persian trade was to be extended through improvement of communications and the building of railways. Public opinion, however, was aroused sufficiently to prevent ratification of this agreement with Britain.

In 1920 the Soviet Union invaded Gilan, the coastal province on the west of the Caspian, and set up a Bolshevik republic. In February 1921, Sayyid Zia-al-Din, a journalist, assumed power in Teheran and called for support of the Persian Cossack brigades. Reza Khan, head of a Persian Cossack regiment, marched on Teheran, overthrew the shah's government, and became minister of war. Four days after the coup d'état, on February 26, a treaty with the Soviet government was signed: the Persian debt was canceled and the Imperial Russian Bank in Persia was turned over to the Persian government; the Julfa-Tabriz Railway was ceded to Persia; all occupied territory was evacuated; and all commercial concessions, except the Caspian fisheries, were annulled.

Zia-al-Din, after 100 days of premiership, fled the country, ousted by Reza Khan, who succeeded in effecting the appointment of Qavam as-Saltaneh as prime minister. Reza Khan immediately set about financing and building up an effi-

cient army which he used to subjugate and disarm the contending tribes and to restore public order. In 1922 a strong financial mission headed by Arthur Chester Millspaugh was brought from the United States to reform Persian finances. In October 1923, Ahmed Shah left for Europe, never to return. Reza Khan appointed himself prime minister and convened the Majlis, which granted him military authority amounting to dictatorship. In 1925 the Majlis elected him *shahinshah* (king of kings). As Reza Shah, he assumed the ancient Persian name of Pahlavi for his dynasty.

Reza Shah. Among Reza Shah's first acts as ruler was an aggressive attack on the Muslim ecclesiastics, who had long enjoyed great precedence and power as administrators of religious law. Under Islamic law, many temporal matters were within ecclesiastical jurisdiction. Reza Shah confiscated shrine lands and incomes, turning them over to the government for the support of secular scholars. He did not attack the Muslim faith, but he suppressed the activities of the dervishes and forbade the annual passion plays which for centuries had inflamed religious fanaticism with their violent pageantry. He sent abroad annually 100 students, and from these he later recruited many of his higher officers and administrators. His most startling social reform was the enforced emancipation of women, which began with the discarding of the veil by students and teachers and the gradual appearance of women at official functions. Within two years the veil had practically disappeared in Persia. By 1935 marriage and divorce laws had been reformed; polygamy, although religiously still legal, was discouraged. Schools for girls multiplied and improved, and women began to enter the professional fields—teaching, nursing, medicine, and even law. See section 2. *The People: Marriage and the Status of Women.*

Reza Shah's most basic change was to reform the law along the lines of the Napoleonic Code. The capitulations (special privileges granted to the citizens of certain foreign nations) were abolished in 1928, and Persia regained her independence in matters of customs and tariffs. After exactly a century, Persia was once more in full control of her territory and borders.

In 1932 the government renegotiated the Anglo-Persian oil agreement. Twenty years later, controversy raged over this pact and its result: whether Reza Shah was in reality a free agent in the final decision and whether on balance the new agreement was or was not more favorable to Iran. Certainly at the time, Iranians regarded the result as a national victory.

Under the vigorous and aggressive leadership of Reza Shah, law and order were maintained, communications vastly improved, modernization in all departments of government encouraged, and national self-respect enhanced. His greatest weaknesses were his passion to establish a dynasty in the Oriental pattern and his personal greed for land, wealth, and power, which inevitably resulted in much injustice to individuals.

World War II. During World War II it was impossible for Iran to remain wholly neutral as the Germans occupied the western USSR and approached Iran's northern borders. The British-Russian position was serious. The oilfields had to be protected and a road opened so that supplies could reach the USSR via the Persian Gulf. On Aug. 25, 1941, following unsatisfactory answers to Allied protests to Iran, British and Russian

forces moved to occupy the south and north, respectively. On September 16, Reza Shah abdicated under pressure, and his son Mohammed Reza Pahlavi succeeded him. On Jan. 29, 1942, the prime minister, Mohammed Ali Foroughi, concluded a treaty of alliance with Britain and the Soviet Union, whereby Iran's territorial sovereignty and integrity and her political independence were assured, with the promise that all alien troops would be evacuated from Iran within six months after the cessation of hostilities or the signing of the peace. On Sept. 9, 1943, Iran declared war on Germany.

Allied occupation, control of imports and communications, and extensive spending, together with a poor harvest, brought cruel inflation and near famine. In recognition of the assistance given the Allied cause, Britain, the USSR, and the United States, meeting in Teheran in conference in December 1943, renewed the pledge of the Tripartite Treaty of Alliance and promised to furnish Iran economic assistance both during and following the war. Meanwhile, an American task force had taken over supply lines from the British and moved more than 5 million tons of material to the Russians in the northern zone, to help fend off the German drive toward the east.

By the autumn of 1944, the major battle lines had moved west, and the Allied military effort in Iran had decreased. When American and British oil companies opened negotiations with the Iranian government for oil concessions in southeastern Iran, the USSR attempted to secure a comprehensive agreement with Iran for the exploitation of all mineral resources (including ore) in the five northern provinces, and for the economic development of that whole area. This was the first skirmish of what came to be the cold war between Russia and the West.

Iran and The Cold War. The Iranian government, supported by the Majlis, responded to the Soviet proposal by forbidding Iranians to enter into negotiations with any foreign company or government for an oil concession. Britain and the United States recognized Iran's right to place this restriction on its citizens, but the USSR did not. In the autumn of 1945 the USSR created the autonomous republics of Azerbaijan and Kurdistan in northwestern Iran, thereby attempting to pressure Iran to accept an oil agreement favorable to Russia. Only the marshaling of world opinion through the leadership of the United States in the United Nations, and the initialing by Premier Ahmad Qavam of a treaty for joint Soviet-Iranian development of the northern provinces prevented the Soviet occupation of Iran in March 1946.

In the autumn of 1946, by a combination of internal and external pressures, the shah and the premier felt strong enough to challenge the Azerbaijan and Kurdistan republics, which vanished almost overnight. The United States ambassador declared that Iran as a sovereign state should decide the oil question on its economic merits without being subjected to any political duress. Supported by this declaration, the Majlis in 1947 rejected Qavam's 1946 Soviet-Iranian agreement by a vote of 102 to 2. The independence of Iran had once more been defended.

Nationalization of the Petroleum Industry. Upon its rejection of the Soviet oil agreement, Iran turned its attention to its seven-year development plan, which began with a survey by the United States engineering firm of Morrison-

Knudsen and which was finally drafted on the basis of a comprehensive study and report by Overseas Consultants, Inc., another United States company. This group was also retained to help carry out the plan, which was to be financed initially by royalties from the rapidly expanding petroleum output of the Anglo-Iranian Oil Company. Before this program could be launched, however, a long-standing dispute with the Anglo-Iranian Oil Company became a dominant national issue.

Attached to the Majlis' 1947 legislation rejecting the Russian oil agreement was a directive to the government to do all it could to bring the Anglo-Iranian oil concession as rapidly as possible into line with the newly declared national policy of the development of Iranian resources by Iranians. Negotiations with the Anglo-Iranian Oil Company finally produced the Gass-Golshayan supplementary agreement, by the terms of which more privileges and royalties were to be granted to the Iranian government. These were deemed quite inadequate by the increasingly influential National Front group of Majlis deputies led by Mohammed Mossadegh. This group increased its influence and power in 1950, and resisted all efforts to secure passage of the Gass-Golshayan agreement. The National Front countered the government's plan by demanding the nationalization of the oil industry.

The climax came when a religious fanatic assassinated Prime Minister Ali Razmara on March 7, 1951. Shortly thereafter the Majlis passed a law nationalizing the petroleum industry. Mossadegh was named premier by the Majlis and formed a government dedicated to the nationalization of the Anglo-Iranian Oil Company (renamed the National Iranian Oil Company, or NIOC, after nationalization), the elimination of British influence from Iranian economic and political life, and the institution of various reforms.

By October 1951, all British technicians had been expelled, and the oil industry had been taken over by Iranians. But only 10 percent of the

Shah Reza Pahlavi has ruled Iran with a firm hand since the overthrow of Premier Mossadegh's government in 1953.

Pictorial Parade

industry remained in operation because Iran was unable to produce and to market the product. In January 1952, British consulates in Iran were closed, and the next September, after Mossadegh won a spectacular political tussle with the shah, diplomatic relations with Britain were severed.

Meanwhile, the United States, aiding Iran just enough to prevent the collapse of its deteriorating economy, first played honest broker between the two disputants, and then joined Britain in direct negotiation. After Iran rejected a final Anglo-American offer in March 1953, the United States made it clear that no further aid would be furnished. A struggle between Mossadegh's government and the shah threatened the throne. But a sudden political change of fortune gave the shah the upper hand and he replaced Mossadegh with Gen. Fazlollah Zahedi as premier on August 18.

Within a year, Mossadegh and many of his adherents were tried, convicted, and jailed. Martial law was proclaimed, and controlled elections were held. Under these conditions, a new oil agreement was negotiated with a consortium originally consisting of eight companies—one British (which retained 40 percent of the stock), five American, one Dutch, and one French. The consortium subsequently was expanded to 17. By the terms of the agreement, profits made within Iran were to be shared equally by Iran and the foreign consortium.

Recurrent Economic and Political Crises. General Zahedi was succeeded as premier by Hussein Ala in April 1955. For the next two years attention centered on reviving and implementing the seven-year development plan (Iranian Plan Organization). The first plan had been brought to a standstill by the drop in petroleum exports after the industry's nationalization. With the reactivation of the industry, economic capital development could be resumed. The second seven-year plan was inaugurated in 1956. Oil revenue was used to finance it, and additional grants to keep it going were obtained from outside the country, particularly from the United States.

In foreign relations, Iran abandoned any pretense of neutrality. She aligned herself with the West by joining the Central Treaty Organization (CENTO), then known as the Baghdad Pact) on Nov. 3, 1955, and summarily rejected all Soviet protests against this action. Simultaneously, the government took measures to curb the outlawed but still active Communist-led Tudeh party.

In April 1957, Manuchehr Eqlal became premier and abolished martial law. In office until August 1960, Eqlal admitted he was only the servant of the shah, who actually ruled. So it continued during the premiership of Sharif-Emami, who remained in office until May 1961.

In 1957-1958 the shah created two political parties—the Milliyyun (Nationalist) party, led by Premier Eqlal, and the Mardom (People's) party, directed by Asadullah Alam. The Mardom party was to be his majesty's "loyal opposition." Many scoffed at this artifice, especially the suppressed real opposition. Elections had been postponed by doubling the Majlis' term to four years, but in August 1960 they were due again. The reorganized National Front and vigorous independents like Ali Amini and Muzaaffar Baghai campaigned against the "regulars," and the hustings got so hot and governmental "rigging" so blatant that the shah felt compelled to cancel the elections and proclaim new ones for early

1961. Amini withdrew, and the National Front was forced to do the same. Yet the 20th Majlis proved unstable and difficult. When public feeling got dangerously tense during a teachers' strike for higher salaries, the shah tried a new tactic. He partially retired from rule, appointed Amini premier, and then dissolved the Majlis.

Premier Amini's first task was to prevent further inflation and to stabilize the economy so that foreign credit could be secured again. But a deep economic recession followed the attempt to achieve stabilization. A budgetary crisis developed and, in July 1962, Amini resigned.

The shah appointed Asadullah Alam premier and himself returned to a more active role in the government. The third plan was put into operation in September 1962. The minister of agriculture, Hasan Arsanjani, continued and greatly accelerated the land distribution program, which had begun in 1950. (See section 3. *Economy: Land Reform*.) In 1963 the shah widened this program to include profit sharing for the city laborers, a massive attack on illiteracy, and new civil rights for women. He also dismissed the now too popular agriculture minister, Arsanjani.

In the spring of 1963, conservative reaction to the intended reforms precipitated violence. The riots, successfully quelled, were largely spontaneous though partly directed by religious leaders. The government claimed that the dissidents had received financial assistance from abroad, presumably from the United Arab Republic.

By midsummer 1963 the shah felt sufficiently confident of public security and his political position to announce new Majlis elections. Since the opposition National Front was not allowed to enter its candidates, the government's candidates, most of whom were approved by the shah and sympathetic to his reforms, won easily. For the first time the urban and reform elements were better represented than the landowners.

In March 1964, Alam was replaced as premier by Hassan Ali Mansur, founder of the court-endorsed New Iran party, which had won the 1963 election. The shah's reform programs were continued by Mansur, and after Mansur's assassination in January 1965, by his successor, Amir Abbas Hoveida.

IRAN, Languages of. There are two categories under which Iranian languages may be considered: (1) the languages of Iran related to the Indo-Hittite or Indo-European languages; (2) the languages of Iran that are non-Indo-European, such as Semitic or primitive Caucasian.

Indo-European Languages.—There is a widely accepted theory that the Indo-Hittite family of languages originally were fairly closely unified in the 2000's B.C. The home of these languages has not been clearly defined, but most authorities indicate the plausibility of regions lying west of the Caspian Sea. In the main branches, such as Indic, Iranian, Hellenic, Italic, Germanic, and Slavic, there are striking similarities in certain words—but there is no common word for *sea*. Late in the 2000's B.C. the unity of the Aryan people, speaking these related languages, seems to have broken up. As these peoples migrated, separate evolutionary trends took place, and borrowing from the peoples whom they conquered contributed to the changes. By about 2000 B.C. there were two rather clearly defined groups: the western Indo-Germanic group and the eastern Indo-Iranian group. The key word used in distinguishing them is the word for "hundred": *centum* in Latin and *satem* in Sanskrit. The *satem* group includes the Slavic, Iranian, and Sanskrit languages.

The migrations which carried the Indo-Iranian languages to Iran and India seem to fit best into the period between 2000 and 1500 B.C. As they wandered around seeking living space, the Aryan tribes drove the primitive inhabitants into hilly or difficult regions and appropriated the better lands for themselves. It was probably in this period that the earliest Indo-European religious hymns were composed. These poems were not reduced to writing until later ages. Passed down by oral tradition for centuries before being recorded, they thus represent the oldest Iranian linguistic tradition. Some of these came to form part of the collection called the Rig Veda (*Rgveda*). Dating back to the middle of the 2d millennium B.C., the Rig Veda represents a compilation of centuries of ritualistic hymns. It was not reduced to written form until the 3d century B.C. (See also BRAHMANISM; INDIA—9. *Languages* and 11. *Literature*; RIG VEDA.)

About the 12th century B.C. several wandering Aryan-speaking tribes invaded the Plateau of Iran. Records of a campaign of the Assyrian king Shalmaneser III show that he met the spearhead of these invaders, called the Medes (Mad or Mat), about 836 B.C. (see MEDIA). They later settled in northwestern Iran. Whether they reduced their language to writing is yet unknown. Rock-cut tombs assigned to the period and supposed to belong to Median aristocracy are without inscriptions. The only surviving terms are names of persons and objects imbedded in documents of a later age. Following them came the Pars (Persians), who had settled in southwestern Iran by the middle of the 7th century B.C. A smaller group, the Khuz, penetrated the plains near the Persian Gulf. The Carmanians, the Sakas (Saca or Shaka), and others settled in central or eastern Iran. These all called themselves Aryans and spoke related tongues. They eventually gave their names to such locations as Hamadan (Hang Mat-an), Fars, Khuzistan, Kerman, and Seistan. Still others occupied eastern Afghanistan, where they established an Iranian dialect of which Pashto (Pushtu) is the modern descendent. It

was made the official language of that country in 1936.

It is worthy of note that the Achaemenid kings, who boasted that they were Aryans, adopted or borrowed from the Medes the title "King of Kings of the Aryan Tribes." When Cyrus the Great (r. 559–529 B.C.) expanded his empire, he referred to it as Iran and An-Iran, the latter referring to the non-Iranian territories. Each tribe had its own king, and the distinguishing factor marking a non-Iranian was his language and tribal affiliation, though these groups were now considered as parts of an Iranian Empire. The name Iran therefore goes back to the 6th century B.C. as the official name of the country. Within this political federation hegemony shifted from tribe to tribe, first from the Mad of the northwest to the Pars of the southwest. After the Hellenic period, the Parthians (Parth or Parti) of the northeast revived Iranian dynastic rule (c. 250 B.C.–226 A.D.), following which it reverted to the Pars again (Sassanid dynasty 226–641 A.D.).

The Old Persian seems to have an eastern (Bactrian) and a western form, perhaps influenced by Median elements. The earliest records of the Old Persian are found in the famous inscription of Darius I (r. 522–486 B.C.) at Behistun (q.v.). It consisted of 36 syllabic signs and 7 other signs. The teachings of Zoroaster, genuine or attributed to him, were collected later in a combination known as the Avesta, or Zend-Avesta. Additional inscriptions are known near Hamadan (ancient Ecbatana), and in 1936 a wealth of material was discovered in the royal Achaemenid palaces at Persepolis and on the Ka'abah, or shrine, of Zoroaster at Naksh-e-Rustam. The language is closely related to Sanskrit.

Alexander the Great allowed most of this literature to be destroyed, and Greek was substituted as the official language during the four centuries of Parthian rule. These kings considered themselves philhellenes and suppressed official expression in Iranian terms. But with the outburst of Iranian nationalism fostered by the Sassanid dynasty, the Old Persian, which had always been the language of the people, reappeared in the form of Pahlavi (Pehlevi), or Middle Persian. One of the main documents is the great inscription found at Paikuli (dated about 293 A.D.). There were dialects such as the Middle Parthian in the north, Middle Sogdian in the northeast (which had a revival in the 9th century A.D.), and Middle Sacian in the east.

The Arab conquest of 641 A.D. imposed Arabic upon Iran, except where heretical groups persisted in preservation of the old literature in secret. A colony of Persians who refused to accept Islam migrated to India, taking their religious books with them, and thus preserved a mass of literature which probably would have been lost in Iran. These Parsis still utilize the Avestic or Pahlavi for their ritualistic devotions.

The great counterreaction to Arabic swept in during the reign of the Samanids (874–999 A.D.), one of the native Persian dynasties. At the court of Mahmud of Ghazni (r. 999–1030), poets vied in a renaissance of Persian. The most famous of Persian patriots, Firdausi (c. 935–1020),¹ composed the *Shah Nameh*, q.v. (*Book of the Kings*) in lyric Persian poetry, eliminating most Arabic words and thereby establishing the style for Modern Persian (c. 1010). It differed consider-

¹Some authorities also give 932 and 934 as possible birth dates, and 1025 as a possible death date.

ably from its parent speech, becoming greatly simplified. Final consonants were weakened; the noun retained only two cases, the nominative and the objective; vestiges of the definite article were kept; and the verb showed similar simplification, there being only two main parts, rather closely related. Tense relations were indicated by the addition of prefixes and auxiliary verbs (*to be, to have*). Person was indicated by suffixes.

The Seljuk Turks invaded Iran in 1037 and soon borrowed the Persian culture. The use of Modern Persian increased in popularity. Travelogues, such as *Safar Nameh* by Nāṣir-i-Khusraw (Khosrau; d. about 1074), the *Siyasat Nameh*, a treatise on government by the celebrated Nizām-al-Mulk (1018–1092), and various studies in geography made their appearance. This was also the age of Omar Khayyām (d. 1123) and the *Rubāiyāt*. An excellent translation of *Tārīkh al-Rusul w-al-Mulūk*, commonly known as the *Annals*, written by al-Ṭabari (838–923), was made in pure Persian.

During the Crusades, Fars took the lead in cultural prominence, developing such outstanding poets as Sa'di (1184?–1291) and Ḥāfiz (d. 1389). Coupled with Jalāl-al-Dīn al-Rūmi (1207–1273), the mystic, and Jāmi (1414–1492), these four and a number of lesser lights raised Persian to a pinnacle whence its influence flowed eastward to the Mogul court in India, Persian becoming the court language of Agra, while westward it was considered a sign of culture in Constantinople (now Istanbul) to be able to read or to write Persian.

The religious influence of Islam, with its preference for Arabic as a divinely revealed eternal tongue, weighed heavily on Persian literature. Arabic was a sign of erudition, wherefore writers too frequently rivaled each other in their effort to use Arabic words, phrases, and idioms. During the 18th and early 19th centuries, Persian became little more than a vehicle for connecting Arabic words. Many compound words appeared—half-Arabic, half-Persian.

After 1852, with the appearance of Naṣr-al-Dīn (r. 1848–1896) of the Kajar dynasty (Turkish), official efforts to simplify Persian appeared. This tendency was accelerated by groups of students who went abroad, especially by a group in Berlin who, after the turn of the 20th century, published *Iranshahr* and other literary magazines of excellent taste. The rise of Iranian nationalism under the vigorous rule of Riza Shah Pahlavi (r. 1925–1941) witnessed a continuing revolt against Arabic culture and an effort to restore Persian to its former glory. An academy was established in Teheran. Its function was to purify Persian from foreign words. Long lists of Persian and Arabic words were issued monthly, the former to be introduced through schools, the press, and the platform, while the latter were strictly prohibited. Unfortunately, the bulk of literature appearing consisted of translations from French and English originals, much of it worthless trash. Yet much original material also saw the light. This trend came to a sudden end on Aug. 25, 1941, when foreign troops invaded Iran; Riza Shah Pahlavi abdicated September 16 and fled, and the academy practically ceased to function.

Aside from the official Persian imposed upon the country by the Teheran government's effort at cultural unification, many Iranian branch languages are alive in peripheral regions. While they retain some archaic forms, in other ways they

have diverged further from the old classic language. Around the southern shores of the Caspian, in the provinces of Gilan and Mazandaran, the common speech is called Gilaki or Talishi. It is reminiscent of the Persian of Sa'di and is spoken by nearly a half million people, but has no significant literature. In eastern Afghanistan, Pashto is being revived as the official language, although Modern Persian has been the vehicle of communication for centuries. In western Iran several languages are discernible. Kurdish is the language of some 3,500,000 people stretching into Iraq, Syria, and Turkey. From the known traces of the ancient Median language, it is suggested that it has been one of the elements in the formation of Kurdish. However, so varied are the Kurdish dialects that some are incomprehensible to Kurds of a distant region. The Mukri dialect is conceded to be the purest. It has developed only a small literature. Probably most voluminous in literary production has been the Sorani dialect of Kermanji (Kurdish), which centers around Sulaimaniya in Iraq. On the periphery, Kurdish has mixed with foreign tongues to form the Zaza in eastern Anatolia (around Siirt) and the Laki near Kermanshah in the South. A courageous effort to use the Latin script has been made by Kurdish leaders in exile in Damascus. The three centers of agitation for development of Kurdish as a means of education are at Mehabad (Saujbulagh) in Iran, Sulaimaniya in Iraq, and Damascus in Syria. In Turkey the central government is making extreme efforts to eradicate Kurdish culture and to impose the Turkish. This movement is complicated by strong political overtones. In Iran also printing of Kurdish literature is prohibited. During the brief Kurdish Republic of Mehabad (1946), there was a flurry of Kurdish literary production encouraged by the donation of a printing press by the Soviet Union, but inasmuch as this material was politically separatist, it was condemned to destruction upon collapse of the regime. Farther south are found the Lurs, whose speech betrays early Iranian origins. West of Isfahan are the Bakhtiari tribesmen, whose speech is reminiscent of old Persian. In the southeast are Baluchi, remnants of age-old Iranian settlers, whose dialect differs from their neighbors. Isolated in the northwest Caucasus are a few thousand Ossetians, descendants of the Alans, whose mountain home has protected them from loss of an Iranian speech, though separated in time and space. Nestled in high valleys, small pockets of vestigial Iranian communities are to be found whose speech sounds medieval. In 1938 Miss Ann K. Lambton published *Three Persian Dialects*, which illustrates this phenomenon. These archaic local dialects have no literature. Tat, a Persian-type dialect, is spoken in the Tarum Valley east of Zenjan, and in isolated mountain villages, such as Harzand north of Tabriz. (See also ASIA—6. Languages [Southwest Asia].)

Armenian remains a puzzle. Recognized as a separate branch of the Indo-European family, it has undergone many changes and includes many Persian loan words borrowed during the Parthian period (250 B.C.–226 A.D.). The lost Armenian sources fused with Caucasian, Old Vannic, and possibly other groups; then, because of the intimate political association in Pers-Armenia during the Parthian and Sassanid periods (c. 250 B.C.–641 A.D.), Armenian took on an added load of Middle Persian terms. It first was reduced to

writing in the 5th century A.D. in the monumental translation of the Bible into the classic (*gerapar*) form. (See ARMENIAN LANGUAGE AND LITERATURE.) Islands of Armenian communities, each using a distinctive dialect, have survived in parts of Iran, but their cultural association has been tied closely to the Armenian community living around the headwaters of the Aras River, where a voluminous literature has been produced. In peripheral regions Armenians have borrowed Turkish or Persian loan words heavily from their neighbors and, in some cases, lost their mother tongue completely. The educated Armenians speak Eastern or "Russian" Armenian, which differs from "Turkish" or Anatolian Armenian.

Non-Iranian Languages.—Iran has been the home of many non-Iranian languages. The earliest recorded language of Iran was Elamite (3d millennium B.C.) with its center at Susa. While records have been scant, one column of the famous Behistun inscription is in Elamite. In 1936 fresh finds of tablets were made at Persepolis. As far as can be determined, Elamite was not related to the Indo-European family.

About the 18th century B.C., there appeared the Kassite Empire. The Kassites, or Cossaeans, left little but a series of names, but these indicate no Indo-European associations.

Following the 9th century B.C., Assyrian kings made repeated raids into western Iran. After the disappearance of the Assyrian Empire, the cultural heritage lived on and, during Christian times, the Eastern Aramaic dialect, called Syriac, became the language of the Nestorian Church, which had several thousand members in northwestern Iran. Numerous religious documents in this branch of the Semitic languages have been preserved. Known in the 8th and 9th centuries as the Peshitta, it is the ritualistic language of the Nestorian Church. Because of World War I, this religious community was scattered and its literature has almost disappeared in Iran. (See also SYRIAC LANGUAGE AND LITERATURE.)

Another of the dead languages used in Iran as an official language was the Babylonian, employed by the Achaemenid kings (550-330 B.C.). It was the third form in the trilingual inscription at Behistun and is found elsewhere in ancient rock carvings. Aramaic (q.v.) was probably the most commonly used language throughout the empire.

In 641 A.D., the Arabs invaded Iran and established Arabic as the written tongue. Iranians did not speak Arabic except in southwest Iran, where tribesmen related to the Arabs of Iraq carried their speech with them. (Vigorous efforts were made by Riza Shah Pahlavi in the 20th century to force a substitution of Persian, but the program was only slightly successful.) (See also ARABIC LANGUAGE.)

The records of the 7th century indicate that Turkish elements were intruding into northeast Iran at that time. Under the middle Abbasid caliphs, Turks were hired as mercenaries to fight the many battles of the caliphs, resulting in the establishment of numerous Turkish-speaking garrisons throughout the Eastern Caliphate. By 1050 the trickle of Turkish migrants became a flood. They settled throughout the north of Iran, and in Anatolia, setting up Seljuk military fiefs, which established Turkish all the way from the Gobi Desert to the Aegean Sea. The Turkic dialects in Iran, of which the Azerbaijani dialect is best known, remain today as the mother tongue

of most of the people of Khurasan and Azerbaijan as well as of the Qashqai tribes in the south. It has had little literary influence, however, though the dominant ruling dynasties of Iran for 700 years have been Turkish-speaking families from the north. This Turkic dialect in Khurasan resembles the speech of the Turkoman tribes of southern Russia and northern Afghanistan. In Azerbaijan, it is more akin to the Turkish of Erzurum. It has borrowed more Persian and considerably less Arabic than the Turkish of Anatolia (Osmanli Turkish). In recent years, the Turkish Republic has sought to revive Turkish words to replace Arabic or Persian loan words and in the small literature of Azeri (Azari) poetry was discovered a rich source of archaic but untainted Turkish. An agglutinized language, it boasts one of the most regular grammars of any language in the world. There is but one principal part to the verb, and syllables representing the tenses, voices, and persons are added to the root in regular order. It is therefore rich in flexibility, expressibility, and clarity. The Soviet Union has adapted it to use with a Russian alphabet, although the Arabic script is also used. In 1944, with the appearance of a Soviet-inspired autonomous revolution in Azerbaijan, this "Azeri" Turki was made the official language of the province, but the permanence of such a practice will depend upon political developments in the future.

IRANIAN LITERATURE. See PERSIAN LITERATURE.

IRAQ, ê-râk' or î-râk' (Arab. AL-'IRÂQ), an Arab republic in western Asia. One of the modern Arab states which arose after World War I from the ruins of the Ottoman Empire, Iraq was formed of three Ottoman vilayets (provinces): Mosul (al-Mawşil) in the north, Baghdad (Baghdād) in the center, and Basra (al-Basrah) in the south. Iraq is bounded on the north by the mountains of eastern Turkey; on the east by the Zagros Mountains, through which runs the Iranian frontier; on the south by the head of the Persian Gulf and Kuwait; on the southwest by Saudi Arabia; on the west by Jordan; and on the north-west by Syria.

Iraq has an area of 171,599 square miles and a population (1957 census) of 6,538,109. The capital, Baghdad, according to the 1957 census, had a population of 852,324; other large cities are Mosul (261,171), Basra (327,593), 'Amara (225,778), and Kirkuk (221,931).

The flag of Iraq consists of three vertical stripes of equal width; the dexter black, the center white, and the sinister green. Centered in the white stripe is a red eight-pointed star. Within the star is a yellow circle bordered in white. The basic monetary unit is the dinar,

1. POLITICAL DIVISIONS, POPULATION, AND CHIEF CITIES

For administrative purposes, Iraq is divided into 14 *liwas* (provinces) and 3 desert administrative districts, the areas, 1957 populations, and capitals of which are given in the following table. See also separate articles on the chief cities.

Divisions	Area square miles	Population	Capital
<i>Liwas</i>			
'Amara	7,096	329,647	'Amara
Baghdad	4,924	1,306,604	Baghdad
Basra	4,747	502,884	Basra
Diwaniya	5,825	507,548	Diwaniya
Diyala	6,224	329,813	Ba'quba
Dulaim	15,751	234,262	Ramadi
Erbil (Arbil)	6,943	272,526	Erbil
Hilla	2,101	353,614	Hilla
Karbala	2,340	217,015	Karbala
Kirkuk	7,859	388,912	Kirkuk
Kut	6,392	290,070	Kut al-Imara
Mosul	11,416	717,500	Mosul
Muntafiq	5,714	455,644	An Nasiriya
Sulaimaniya	3,685	299,978	Sulaimaniya
<i>Desert administrative districts</i>			
al-Jazira Desert	12,056		
North Desert	39,127		
South Desert	29,399		

2. THE PEOPLE

The population of Iraq is not particularly homogeneous. Divided by native language, it breaks down roughly into 79 per cent Arabic, 16 per cent Persian, and 2 per cent Turkish. Arabic is the official language; English is widely spoken as a second language among commercial, professional, and governmental personnel. Over 90 per cent of the total population are Muslims (Moslems), a little more than half of whom belong to the Shi'ite sect rather than the orthodox Sunni group. The latter consists, generally speaking, of the Arabs of the north, the Bedouins, the Kurds, and the inhabitants of Baghdad and Basra. The Shi'ites are concentrated among the Arabs of the south and the Persian-speaking groups. They are especially associated with the holy cities of al-Najaf, Karbala, and Kadhiman (al-Kāzimayn). Christians, who numbered 150,000 in 1947, are mainly of Nestorian, Jacobite, and Gregorian sects. Most of the 118,000 Jews listed in the 1947 census have emigrated to Israel; in 1958 only about 10,000 remained in Iraq. In addition to the linguistic and major religious divisions there are other isolated and fossilized groups such as the Ma'dan, marsh dwellers of the south; the Sabaeans; and the fire-worshipping Yazidis of the north. See also ASIA—6. *Languages* (Southwest Asia); MOSLEM SECTS.

3. THE LAND

Iraq is composed of three main geographical divisions: steppe and desert in the south and west, lowland and plain in the Tigris-Euphrates Valley, and highland and mountains in the north and northeast. The physical scene is dominated by two long and inundating rivers, the Tigris and the Euphrates, both of which rise in Turkey. They follow courses of 1,150 and about 1,700

Chapelle from Monkmeyer

Iraqi children, including a baby in a burlap crib.

miles, respectively, and join to form the 115-mile Shatt-al-Arab, which empties into the Persian Gulf. In their lower courses water may be conducted from one river to the other, thereby increasing facilities for irrigation. With the melting of snow at their sources, both rivers begin to rise in the spring, reaching their maximum in April and May. Vast areas are thus regularly inundated, but at times floods go out of control and cause considerable damage. Modern flood-control projects, such as the Wadi Tharthar overflow, will, however, probably completely eliminate destructive floods. This inundation compensates for the scarcity of rain, which averages less than 10 inches annually. In Baghdad the average rainfall is only 5.9 inches; in Mosul, 14.6 inches. The northeast highlands receive 15 to 25 inches. In summer the shade temperature exceeds 110° F. For July and August, the two hottest months, Baghdad averages 92°; for January, 48.8°.

These physical conditions have hindered the natural growth of population, interfered with communications, and isolated certain communities. Roads are subject to destruction by sudden floods, and in their higher reaches the rivers are navigable only downstream. Only 3 per cent of the total area of the country is cultivable. Unirrigated sections are almost devoid of vegetation, but along the river banks and canals date palms grow in abundance. In addition to the world-renowned fruits, the palms yield construction materials and fuel. Poplars are also conspicuous.

4. ECONOMIC DEVELOPMENT

Agriculture.—Some 80 per cent of the people of Iraq derive their living directly or indirectly from the soil. Nomads, seminomads, and sedentaries also raise a variety of crops. Barley and wheat are the staples. Other cereals include rice, corn, millet, and sorghum. Aside from dates, fruits comprise pomegranates, oranges, apples, apricots, and lemons, which grow largely in north-

ern and northeastern areas. It is estimated that over 18 million date palms of fruitbearing age, mostly along the Shatt-al-Arab, make Iraq the world's largest producer of dates; the country is responsible for some 80 per cent of the commercial supply. Some nuts and olives are also produced, and between 1951 and 1956 annual cotton output ranged from 1,000 to 8,000 tons. Tobacco is also grown.

Industry and Trade.—Oil is the only mineral extensively exploited and this industry ranks first in Iraq. In 1955 the total production was 33,149,200 long tons; 1956 production dropped to 29,469,100 long tons because of pipelines cut in the Suez crisis. The oil operations are, with minor exceptions, carried on by the Iraq Petroleum Company, Ltd. (IPC) and its subsidiaries, the Basra Petroleum Company and the Mosul Petroleum Company. The IPC concession dates from 1925;¹ revised in 1952, it provides for a "50-50" split of profits between the government and the company. Based on annual production of 30,000,000 tons, Iraq receives approximately \$200 million per year. Oil is exported by tanker from Basra and by pipelines to the Mediterranean coast. A 12-inch pipeline from Kirkuk to Haifa, Israel, and one from Kirkuk to Tripoli, Lebanon, were installed in 1934, but the Haifa line has not been in operation since the establishment of Israel in 1948. An additional 16-inch line to Tripoli was opened in 1949. In 1952 a 30-inch line from Kirkuk to Baniyas, Syria, was opened. Syrian sections of these pipelines were blown up during the Suez crisis of November 1956.

Other industries in Iraq are of relatively minor importance, but include the supplying of electricity and water, and the manufacture of bricks and cement. There are also food processing industries, such as breweries and date packing; cigarette, spinning and weaving, chemical, furniture, clothing and metalworking industries. However, out of a total of 22,460 establishments employing 90,291 workers in 1954, only 294 employed more than 20 persons.

Oil is obviously the chief export (\$438,796,000 in 1956), followed by barley (\$13,958,000), dates (\$6,952,000), wool (\$4,408,000), and six other products (total \$6,440,000). The principal imports are machinery, iron and steel products, motor vehicles and parts, textiles, wheat, sugar, and tea. In 1956 imports totaled \$317,520,000.

Transportation and Communications.—Historically, internal water transportation has played an important role in Iraq's economy. The Tigris is navigable by shallow draft vessels from Basra to Baghdad, and with difficulty by small craft as far as Mosul in the high-water season. The Euphrates is navigable to a very limited degree, but in any case alternate methods are making most water transport obsolete. The port of Basra is of key importance and in 1954 handled 1,219,117 metric tons of cargo. Both Baghdad and Basra enjoy modern airport facilities, and in mid-1957 a new Baghdad airport was begun. The government-owned Iraqi Airways operates throughout the Middle East and to Europe. In 1958 some 12 other airlines, including 2 United States lines, served the country. The Iraqi State Railways operate a meter-gauge line 691 miles long, con-

necting Basra with Erbil via Baghdad and Kirkuk, and a standard-gauge line 403 miles long running from Baghdad and connecting with the Syrian system via Mosul. Highways have until recently been mostly unsurfaced dirt roads subject to frequent washouts in winter, but a number of major bridges and roads have recently been completed or are under construction. A 1956 estimate was that Iraq had 1,800 miles of hard-surfaced roads (of which the longest is that from Baghdad to Jordan) and 5,000 miles of unimproved roads. The new projects link the major cities and total approximately 1,500 miles in length. Five major bridges have recently been completed, and others are contemplated. Baghdad is the only major Arab city boasting television; sets numbered 600 at the end of 1956. See also BAGHDAD RAILWAY.

The Development Board.—Most of the new, large-scale development projects in Iraq, such as roads, bridges, airports, and river control, have been carried out under the aegis of the Economic Development Board. Created in 1950, this board is a tremendous new force in the country. By law, 70 per cent of all oil income is allocated to the board to finance its projects, and, according to plan, the board expected to spend some \$1,400 million in the six-year period of 1955-1960. About 30 per cent of this vast sum was allocated to river control. The purpose is to provide water for irrigation, to prevent devastating floods and, to a lesser degree, to provide for hydroelectric power. Irrigation by modern methods began as long ago as 1908, when the Hindiya Barrage was begun. Other works followed, but the Development Board's plans overshadow everything else. The four main river projects are: the Samarra Barrage, which diverts water into the Wadi Tharthar depression to the southwest (completed spring 1956); the Habbaniya (Habbāniyah) Reservoir, including the Ramadi Barrage (completed in 1956); the Dokan (Dūkān) Dam (construction began in 1957, completion planned for 1958); and the Derbendi Khan (Darbandi Khān) Dam (projected for completion in Iraq at a cost of over \$50 million. It is believed that these four projects will give ample protection against floods and suffice for irrigation needs. There has been, however, some criticism of the board for neglecting aspects of agricultural development, such as rural extension services. Other areas getting massive support from the Development Board are transportation (roads, bridges, railroads, ports, and airports); industry, mining, and electricity; public housing and public buildings.

5. GOVERNMENT

Prior to the revolution of July 1958 the Iraqi government was an hereditary constitutional monarchy on the British model with authority vested in the noble Hashemite family of Hejaz. After some days of martial law, the republican government announced a provisional constitution under which the country would be run by a sovereignty council composed of three members. The Council of Ministers was empowered to legislate as well as to assume executive powers. The constitution also provides for Islam as the state religion, freedom of worship and expression, the maintenance of private property, and an independent judiciary.

Each of the 14 *liwas* into which the country is divided is under a governor (*mutasarrif*) responsible to the minister of the interior. Each *liwa* is divided into a number of *qadas* (districts),

¹The ownership of IPC comprises: Standard Oil Company of New Jersey, 11.875 per cent; Socony-Mobil Oil Company, 11.875 per cent; British Petroleum, 23.75 per cent; Royal Dutch Shell Company group, 23.75 per cent; and the estate of the late C. S. Gulbenkian, 5 per cent.

Above: Baghdad on the Tigris. In the 9th century Caliph Harun-al-Rashid of "Arabian Nights" fame made it the most splendid city of Islam. Today, capital and chief city of Iraq with over a million inhabitants, it has a modern aspect while retaining mementos of its colorful past.

IRAQ

Right: Few women in Iraq can read and write, and almost as few men. To help the great masses of the people who are still illiterate, a scribe sits outside every post office and sells his service to all comers.

Center left: A statue of the Sumerian high priest Du-Du, carved some 4,600 years ago. Excavations are continually bringing to light such relics of ancient Mesopotamian culture.

Center right: White marble statues of the Sumerian god Abu and his consort. Found at Tell Asmar, a rich archaeological site, they date from the early dynastic period of about 2800 B.C.

Below: Excavations at Eridu revealing the remains of a pyramidal temple tower which dates from the period 4000-2000 B.C.

and these in turn into *nāhiyahs*.

Justice is administered by courts of various grades. In addition to civil courts, which handle civil, criminal, and commercial cases, there are religious courts that deal with matters of personal status, such as marriage, divorce, inheritance, and adoption.

Military service is compulsory for all men between the ages of 18 and 25 and lasts from 18 months to 2 years. Iraq is defended by the army, air force, police, and a small navy. A volunteer "people's resistance" organization was formed by the republican government.

6. EDUCATION

Education in its early stages is free but lacks adequate facilities for universal implementation.¹ In 1959-1960 there were 3,228 primary schools and 362 secondary schools with a combined enrollment of 762,820; also 5 institutions of higher education with over 12,000 in attendance. Slightly under 25 percent of recent budgets is allotted to education. In secondary education a distinction is made between curricula for girls, which stress child care and domestic science, and those for boys, of which scientific, literary, and commercial courses constitute the core.

Although it has lagged somewhat behind some other Arab states in the establishment of a university, nevertheless a number of separate faculties were developed after World War I, and the government of Iraq, by an act of Parliament of June 1956, united them as the University of Baghdad. It includes the following major divisions: arts and science, fine arts, medicine, Muslim law, agriculture, commerce and economics, engineering, scientific and industrial research, higher teachers' training, law, Queen 'Aliyah College for girls, and veterinary science. A second university, al-Hikmah, run by American Jesuits, and an outgrowth of their secondary school, Baghdad College, is also in Baghdad. Newspapers and periodicals are published, mostly in Baghdad, and there are a number of libraries and important museums, also located in the capital.

7. HISTORY

Mesopotamia, as Iraq was formerly called, was one of the earliest seats of culture. The nomadic Semites who moved there about 3500 B.C., presumably from the Arabian Peninsula, encountered an already high civilization, that of the Sumerians, who lived in homes, cultivated the land, and possessed a highly developed system of writing known as cuneiform. Those Semites who settled in the southern part of the country became known as Babylonians, after their capital city of Babylon; those in the north were Assyrians, with Nineveh (near modern Mosul) as their capital.

For a detailed account of the ancient history of Mesopotamia, see *ARCHAEOLOGY—Old World*; *ASSYRIA*; *ASSYRIOLOGY*; *BABYLONIA*; *MESOPOTAMIA*; *MIDDLE EAST*; *ORIENTAL ARCHAEOLOGY—Mesopotamia*.

In medieval times, Iraq was the seat of the Abbasid ('Abbāsīd) caliphate, the longest lived (750-1258) and best known of all Muslim caliphates. It enjoyed its golden age under Hārūn al-Rashīd (r. 786-809), of *Arabian Nights* fame, and his son al-Ma'mūn (r. 813-833). Under these two rulers, Baghdad was the center of a transla-

tion movement, mainly from Greek, which embraced the major works in philosophy, medicine, mathematics, astronomy, and geography. Following their reigns, the caliphate began to disintegrate. See also *ABBASIDS*; *ARAB PHILOSOPHY*.

With the capture of Baghdad in 1258 by the Mongol Hulagu and the attendant massacre of the population and destruction of the canals, the country entered upon a period of decline that reached its nadir under the Ottoman Turks. The 380-odd years of Ottoman rule were characterized by wars with Iran, raids from the desert, sectarian disputes, and quasi-independent local chiefdoms. The enlightened but brief governorship of Midhat Pasha (1869-1872) did not suffice to reverse the tide of degradation. By the time of World War I some Iraqis, especially army officers, were infected with the Western nationalistic ideology.

The modern history of Iraq begins when the British took it from the Turks in World War I and subsequently established a British mandate. In 1921 Faysal (Faisal), third son of King Ḥusayn (Husayn ibn-'Alī) of the Hejaz was, with full British approval, proclaimed king of Iraq. A moderate, he led the fledgling state cautiously but persistently toward independence. The first Parliament met in 1925. In 1932, Iraq was admitted to the League of Nations and thus obtained formal recognition as an independent sovereign state. A 1930 treaty with Great Britain had replaced the mandate and provided, among other things, that Britain could keep two airbases in the country. In 1933 Faysal was succeeded by his son Ghāzi I, who was killed in an automobile accident after a reign of six years. Thereupon, Ghāzi's infant son Faysal was proclaimed his successor under the regency of his maternal uncle 'Abd-al-Ilāh. In 1953, on attaining his majority, he was enthroned as Faysal II and reigned until his assassination in 1958.

The newly independent Iraqi state had considerable difficulty in stabilizing itself. The Assyrian troubles of 1933, and the tribal revolts of 1935-1936 were both symptomatic. There was, in addition, rising feeling against Great Britain because of its sponsorship of Zionism in Palestine—feeling which was increased by the propaganda barrage from Nazi and Fascist sources. Several coups d'état culminated in the brief pro-German coup of Rashīd 'Alī al-Gailani in 1941. Expected Nazi help did not arrive in quantity, and British forces put down the uprising with little difficulty. Thereafter Iraq observed the terms of the Anglo-Iraqi alliance of 1930, and in 1943 declared war on the Axis. In 1945, Iraq became a charter member of the United Nations.

Another international organization in the founding of which Iraq, under the leadership of its veteran premier Nūrī al-Sa'īd, played a leading part was the Arab League (q.v.). As Egypt became the leader of a "neutralist" orientation in the Arab world, Iraq was identified as the leader of the pro-Western policy. In February 1955, Iraq signed an alliance with Turkey; Great Britain, Pakistan, and Iran followed suit in subsequent months, thus completing membership in the Baghdad Pact, so called because its permanent secretariat was established in that city. The United States, although a member of various committees, was not a formal member of the alliance.

The Anglo-French-Israeli invasion of Suez in November 1956 almost sundereed the pact because of the depth of pan-Arab feeling in Iraq, but the

¹ In 1947, 89 percent of the sedentary population over 5 years of age was illiterate. The percentage is doubtless declining steadily.

government emerged committed to the West and also to common Arab ideals. These ideals were, however, exploited more effectively by President Gamal Abdel Nasser (Jamāl 'Abd-al-Nāṣir) of Egypt. When, therefore, Syria and Egypt united as the United Arab Republic (Feb. 21, 1958), Iraq hastily formed (May 12) with the Hashimite Kingdom of Jordan a new merger, the Arab Union. On July 14 a military coup headed by Abdul Karim Kassem ('Abd-al-Karīm Qāsim) killed Nūrī al-Sa'īd, King Faysāl, and his uncle regent, and proclaimed a republic with Kassem as premier. The new regime banned political parties, withdrew from the Baghdad Pact, and accepted financial and technical aid from the Soviet Union. In June 1961, Kassem laid claim to Kuwait on historical grounds, but received no support from other Arab states; and when their league admitted Kuwait, Iraq boycotted it. Because the United States recognized Kuwait's independence, Kassem broke off diplomatic relations on the ambassadorial level. Meanwhile, the Kurds, who formed about 15 percent of an estimated (1960) 7,085,000 population, were intensifying their rebellion in the north and straining the financial and military resources of the republic. Syria's secession from the United Arab Republic in September 1961 drew it closer to Iraq, which in June 1962 signed a trade agreement with it.

On Feb. 8, 1963, another military coup, headed by Col. Abdul Salam Aref ('Abd-al-Salām Arif), destroyed the Kassem regime and the following day executed him by a firing squad. Aref was a deputy of Premier Kassem's but belonged to the Socialist Ba'th (Baath, renaissance) Party which favored union with Egypt. After the Baathists fell out with Nasser in May, Aref broke with them and seized control himself, with army support, in November.

IREDELL, ir'dēl, James, American jurist: b. Lewes, England, Oct. 5, 1751; d. Edenton, N.C., Oct. 20, 1799. He migrated to America in 1768 as comptroller of the customs at Edenton. Meanwhile, he studied law and was licensed in 1771. From 1774 to 1776 he served as collector of the port of Edenton, and in 1777-1778 as judge of the state superior court. He was attorney general of North Carolina from 1779 to 1781, and in 1787 was elected to the Council of State. As a

delegate to the convention of 1788, he supported ratification of the federal Constitution. He was appointed to collect and revise the acts of the legislature; his *Revisal* was published in 1791. From 1790 until his death he served as associate justice of the United States Supreme Court, for which he wrote a number of notable opinions, the best known of which, in *Chisholm v. Georgia*, ably defended states' rights.

IRELAND, ir'länd, John, American prelate: b. Burnchurch, County Kilkenny, Ireland, Sept. 11, 1838; d. St. Paul, Minn., Sept. 25, 1918. In 1849 he emigrated to the United States with his parents, who settled in St. Paul in 1853. He was sent to France to study theology at the seminaries of Meximieux and Hyères, and following his return to St. Paul in 1861 he was ordained in the Roman Catholic priesthood. In 1862-1863, during the early stages of the American Civil War, he served as a chaplain in the Union Army. He was appointed rector of the cathedral at St. Paul in 1867, and in 1875 he became coadjutor bishop. In 1884 he was made bishop, and in 1888 he was consecrated the first archbishop of St. Paul. He was influential in securing the founding of The Catholic University of America in Washington, D.C., and a leader in the spread of parochial schools in the United States.

IRELAND, William Henry, English literary forger: b. London, England, 1777; d. there, April 17, 1835. He imposed spurious Shakespearean manuscripts upon his father, Samuel Ireland, a bookseller and engraver, who was a Shakespeare enthusiast, and also upon other men of letters. These documents included a transcript of *King Lear*, extracts from *Hamlet*, and the pseudo-Shakespearean plays *Vortigern* and *Rowena* and *Henry II*. *Vortigern* was purchased by Richard Brinsley Sheridan and produced by him in 1796 at Drury Lane, where it proved to be a complete failure. The forgeries were detected by Edmund (Edmond) Malone (q.v.), and Ireland acknowledged the fraud in his *Authentic Account of the Shakespearean Manuscripts* (1796); in his *Confessions* (1805) he gave a more detailed account of his forgeries, removing the suspicion that his father may have been an accomplice. *Vortigern* and *Henry II* were published in 1799, and *Vortigern* again in 1832. He also wrote several original romances, ballads, and narrative verse. Ireland's career formed the basis of a novel by James Payn, *The Talk of the Town* (1885). His father's correspondence concerning the forgeries, as well as some of the specimens of the latter, are in the British Museum.

IRELAND, an island, separated from England on the east by the Irish Sea and St. George's Channel, covers 31,840 square miles, of which 26,602 square miles are in Eire (Republic of Ireland) and 5,238 square miles in Northern Ireland. (See IRELAND, REPUBLIC OF; NORTHERN IRELAND.) It is divided into 32 counties, formed gradually from the 11th to the 16th centuries. These counties are by tradition grouped into four provinces as follows—LEINSTER PROVINCE: Carlow, Dublin, Kildare, Kilkenny, Leix or Laoighis (formerly Queen's County), Longford, Louth, Meath, Offaly (formerly King's County), Westmeath, Wexford, Wicklow; MUNSTER PROVINCE: Clare, Cork, Kerry, Limerick, Tipperary, Waterford; CONNACHT (or CONNAUGHT) PROVINCE:

Galway, Leitrim, Mayo, Roscommon, Sligo. ULSTER PROVINCE includes three counties of Éire—Cavan, Donegal, and Monaghan—and the six that form Northern Ireland—Antrim, Armagh, Down, Fermanagh, Londonderry (or Derry) and Tyrone. Confusion is caused by the fact that the word "Éire" is the Irish for Ireland and may, with equal validity, designate the entire island or the 26 southern counties; while "Northern Ireland" is often referred to as "Ulster" though it consists only of six out of the nine counties within that province.

Topography.—Most Irish views include mountains as at least a distant background in the landscape, and it is the variety of scene that gives the country its scenic attraction. There are no mountains of great height, and the loftiest, Carrauntoohill (Carrantuohill), 3,414 feet, is in the Reeks of Kerry (Macgillcuddy's Reeks): but in several of the major mountain ranges deep valleys, heath-covered moorlands, and occasional lakes combine to give an impression of rugged grandeur. Nowhere is this more vividly seen than in the extreme west of Connacht, where the Twelve Bens (misnamed Pins) of Bunnabeola in Connemara rise to over 2,000 feet above many square miles of peat bogs on ground only 100-200 feet above sea level. In Achill Island, similar sharp hills over 2,000 feet high rise precipitously from the sea itself; and Slieve League, in the extreme southwest of Donegal, is equally impressive. Several of the mountainous parts of Ireland, visited most by tourists, are close to the sea. In Donegal, western Connacht, and Kerry, mountain ranges are penetrated by long marine inlets, varied in form but everywhere making a scene of great beauty. In the east, the major range is the Leinster chain, which extends for 70 miles southwestwards from Dublin, parallel to the coast: this range has various local names, such as the Dublin Mountains (near the city), the Wicklow Mountains (in the county of the same name), and the Blackstairs Range. The highest peak is Lugnaquilla, 3,039 feet, and there are several fine valleys such as Glendalough, as well as high-lying moors of wide extent. The Mourne are a sharp range in County Down, which rise to 2,796 feet in Slieve Donard direct from sea level: the range has some remarkable deep valleys. North of Belfast, there is an upland, the Antrim plateau, mostly 1,000-1,500 feet high but intersected by several valleys known here as "glens" and separated from the sea only by a very narrow lowland traversed by the Antrim coast road. Less spectacular but interesting plateaus are formed of Carboniferous rocks in the Castletomer upland (between the Barrow and Nore rivers), the uplands on either side of the lower Shannon (parts of counties Cork, Limerick, and Kerry, and those to the west of County Clare), and a group of uplands in County Sligo and adjacent counties. These plateaus are mainly 1,000-2,000 feet high and include among their strata some of coal measure age, though most of these are unproductive and only in Castletomer is there any mining of significance.

Physical maps reveal at once that the uplands of Ireland have two marked trends. In the extreme south, the hills run east-west, finally reaching the Atlantic in a series of peninsulas: elsewhere, however, the hills run from northeast to southwest, as in the Leinster chain, the Slieve Bloom, and other ranges in the southern half of

Ireland, in the Mourne Mountains, and in the sharp-peaked ridges of the northwest. Around the mountains there are lowlands, covering in all more than three quarters of the whole island. The greater part of these lowlands is floored by Carboniferous rocks, but some are developed on earlier strata, and their variety of surface form is due to a complex glaciological history. Almost the whole area of Ireland was covered by ice at some phase in the Quaternary Ice Age, and drifts of varying thickness, some very shallow but others as much as 200 feet deep, occur over large areas: in the lowlands north and south of Galway Bay, however, drifts are absent and remarkable expanses of bare limestone are seen, some devoid of vegetation, but others with low-growing hazels and occasional ash trees. A major effect of the glaciation was the disorganization of the drainage, for peat bogs were formed widely in the Central Lowland and lakes filled hollows, of which some had been ground out by the ice and others lie between various glacial deposits. And not the least remarkable feature is a belt of drumlins (see *Geology*, below) occurring mainly in a band of country 50 miles wide from the Ards Peninsula (south of Belfast Lough) westward to Clew Bay, County Mayo, with extensions through the Erne Valley to Donegal Bay. They are also numerous in the Bann Valley.

Coastlines are varied in form. In the east there are rocky shores and cliffs, some of which have splendid exposures of glacial drift. Wexford Harbour, Dublin Bay, Carlingford Lough, Strangford Lough, and Belfast Lough are the major inlets; at various points along the coast there are sand dunes. The south coast has several long inlets—two of which form the harbors of Waterford and Cork: much of the coast has cliffs some 200 feet high, broken by numerous estuaries and coves. In the west, there is some magnificent coast scenery. Western Cork and Kerry consist of peninsulas with hills, some of which terminate in high cliffs, and islands add variety to the scene. The long estuary of the Shannon is tidal to Limerick, 50 miles from the open sea. County Clare has some fine cliffs, notably the Cliffs of Moher, which have a vertical drop of 600 feet. Limestones in north Clare and in the Aran Islands are exposed in horizontal slabs, seared by weathering into pavements. In Galway Bay, there is a marked contrast between the limestones to the south and the ancient metamorphic rocks to the north; and in the west there are numerous islands. This scenic type is continued northwards to Clew Bay, where the drumlins, at the western extremity of their great spread across Ireland, appear as a multitude of islands. Quartzites, highly resistant metamorphic rocks, form massive precipices almost 2,000 feet high in Achill Island and in the southwest of County Donegal; but otherwise the coasts of this area are varied in form, though including numerous cliffs. Four long inlets of County Donegal—Lough Foyle, Lough Swilly, Mulroy Bay, and Sheep Haven—add to the variety of an intricate coastline. As a whole, the coasts of Ireland are remarkable for their scenery and variety.

Hydrography.—Rivers have complicated courses in Ireland, due to an involved geological history and the deposition of large quantities of glacial drift. A puzzling feature is that certain rivers flow over the Central Lowland in courses almost level, and then fall rapidly to sea level in their last few miles. The Shannon, for example,

falls 100 feet in the last 16 miles from Lough Derg to the tidal level at Limerick, and there is a similar fall at Ballyshannon, on the Erne: both these falls have now been used for hydro-electric stations. Several other rivers, such as the Liffey, the Barrow, and the Nore, flow through gorges for many miles before they reach the sea.

The Shannon, the longest river in the British Isles, rises in the Carboniferous uplands near Sligo Bay, falls steeply to Lough Allen (164 feet), and then flows gently across the lowland; it passes through several lakes, of which the two largest are Lough Ree and Lough Derg. Its three major tributaries, the Suck, Inny, and Brosna, are similar slow-flowing lowland rivers. The Erne, which flows to Donegal Bay, is a river draining an intricate drumlin country marked by numerous lakes, of which the two largest are upper and lower Lough Erne. In the north, the Foyle-Strule river system consists of one main stream and several tributaries; the Bann rises on the north side of the Mourne Mountains, and flows northward, including in its course Lough Neagh (150 square miles), the largest lake in the British Isles. The Boyne and its tributary the Blackwater drain eastern parts of the Central Lowland, and the Liffey rises in the Leinster chain and winds round the west side of these mountains to reach the sea at Dublin. Only one river, the Slaney, cuts through the Leinster chain.

The rivers of the south and southeast have courses of great interest. The streams flowing to Waterford Harbour—the Barrow, Nore, and Suir—pass through peat bogs on wide lowlands in their upper courses, but entrench themselves in gorges as much as 100 feet deep nearer the sea. From a point near Clonmel, the Suir has an west-east course, a feature seen also in rivers still farther south—the Blackwater, its tributary the Bride, the Lee and (another river) Bride at Cork, the Bandon, and numerous smaller streams. All these rivers flow in valleys between the east-west chains of mountains to which reference has already been made: the Blackwater and the Lee turn south and reach the sea in striking estuaries. Most of the remaining rivers are short and insignificant.

As a whole the rivers of Ireland have great interest for the physical geographer: in the Central Lowland they are sluggish, slow-moving streams bordered in places by extensive peat bogs, but in the lower reaches they are swifter-moving, pleasant stretches of water. Few visitors trouble to explore these valleys, but the Foyle, the Boyne in County Meath, the "three sisters" (Barrow, Nore, and Suir) which unite in Waterford Harbour, the Blackwater, and, to quote Edmund Spenser, "the spacious Shenan (Shannon) spreading like a sea," all have their distinct beauty.

Geology.—The oldest areas of Ireland are the pre-Cambrian masses, comparable to those of the Scottish Highlands, in the northwest (counties of Donegal, Londonderry, and Tyrone) and in the west of the Connacht Province (western Mayo and western Galway). Within these areas, there are varied rocks, including gneisses, schists, granites, and quartzites; and it is the last of these that form some of the striking hills, including some sharp conical peaks such as Errigal in County Donegal, Nephin in County Mayo, the Twelve Bens (or Pins) of Connemara, and the Maamturk Mountains, both in County Galway.

As a whole, these areas of ancient rocks include both mountains and lowlands in a complex intermixture, and additional topographic variety is given by the marine inlets and fragmented coast-lines.

Caledonian mountains, formed by earth movements in Silurian and Devonian times (over 300 million years ago), include the ranges of County Donegal and County Derry, where the hills have a clearly-marked northeast-southwest line: seen especially in the Sperrins, in Donegal it is accentuated by the existence of deep valleys between each range. In County Sligo, the Ox Mountains have the same northeast-southwest trend, but it is less clear in County Mayo and County Galway. On the east side the hills from the south of Belfast Lough inland almost to the Shannon have the same trend, but there are few sharp ranges except for the Mourne Mountains of County Down, where granites of a late date (Tertiary) formed a line of hills having the same Caledonian northeast-southwest line. In the southeast, the Caledonian movement was accompanied by an uprising of granite, and the Leinster chain (parts of which are also known as the Wicklow Hills, the Blackstairs Mountains, and Mount Leinster) consists of a vast anticlinal arch: after many millennia of erosion, the granites have been exposed in the center and the Silurian and older rocks left on either side. The Caledonian ranges have numerous peaks over 2,000 feet, and in County Wicklow, Lugnaquilla, as has been noted, is 3,039 feet high: the northeast-southwest line is a major feature in the physical geography of Ireland, not only in the west but in the east, particularly in the Leinster chain, which is broken as a range by only one river, the Slaney.

After the mountain-building storms, a period of slow accumulation followed in which Devonian and Carboniferous strata were laid down. Some of the Devonian beds, known as Old Red sandstones, were later to offer great resistance to erosion, greater in fact than either the older Silurian and Ordovician beds or the newer Carboniferous strata. A further mountain-building period, the Armorican, followed in Carboniferous and Permian times, and some remarkable mountain ranges were formed in consequence. Of these, the clearest are the long east-west lines of hills which extend from County Waterford to the peninsulas of Kerry: in these ranges the highest ground is formed of the Old Red sandstones—mentioned above as strongly resistant to erosion. In these ranges there are some high peaks, including Carrauntoohil (Carrantal), 3,414 feet, the highest point in Ireland, and Galtymore, 3,018 feet. Where the Old Red sandstones have been removed by erosion, upland basins exist, flooded by older Silurian and Ordovician rocks: the Comeragh Mountains formed of Old Red sandstone, for example, rise as a craggy range above such an upland basin. In the valleys, Carboniferous limestones are exposed. In the extreme south, the Old Red sandstones exist in ridges, 600-800 feet high.

South of a line drawn from Dungarvan to Dingle Bay, the Armorican ranges are continuous from east to west except for a few gorge-like stretches of river valley, notably that of the Blackwater from Cappoquin to Youghal. Many of the rivers flow in west-east valleys for the greater part of their course; and the Blackwater is an excellent example. North of the Dungar-

van-Dingle Bay line, the ranges are isolated from one another by extensive lowlands: these include the Slievenaman Range, the Comeraghs, the Knockmealdowns, the Galtee Mountains and the magnificent ranges of the Dingle peninsula. In structure these ranges are similar to those farther south, but the intermingling of lowlands makes them even more impressive in appearance. Everywhere the east-west line prevails, and is as marked a feature of Irish topography as the northeast-southwest line of the Caledonian folds.

In one long and variously named series of hills, extending from the neighborhood of Limerick, where it is called the Slieve Felim, to the Slieve Bloom, near Maryborough, Armorican ranges of similar structure to those farther south are aligned from northeast to southwest—that is, parallel with the Caledonian chains. Grenville Cole suggested that these Armorican mountains have been folded over previously-existing Caledonian chains.

Carboniferous rocks cover over half the area of Ireland. There is a full range of strata: over most of the country, Carboniferous limestones occur, and all the younger strata have been removed, but three plateaus of coal measures, millstone grits, and upper limestones remain. Of these, the first is the Castletomer—Slieve Ardagh plateau; the second, the Munster "coalfield" extending from Killarney to Galway Bay; and the third, the plateaus extending from County Sligo to County Monaghan. Although coal measures form part of these plateaus, they contain very little coal. The Castletomer—Slieve Ardagh area has limited resources of anthracite, but in the so-called Munster coalfield, the seams are thin, heavily faulted, and almost valueless. There is a small coalfield in the third plateau area, in the Arigna district beside Lough Allen. As elements in the landscape of Ireland, these plateaus are of no particular attraction: but they have long even skylines of considerable interest. The Castletomer plateau is some 1,000 feet high and the Slieve Ardagh (separated from Castletomer by the Nore Valley) reaches similar altitudes. The Munster plateau is divided into two by the Shannon, and on the south has long even skylines, 1,000-1,200 feet high, rising to over 1,400 feet; in County Clare, hills of similar height exist. The Sligo-Monaghan plateaus are divided into a number of parts by deep valleys, above which they rise to 1,500-2,000 feet.

The Central Lowland of Ireland is floored almost entirely by Carboniferous limestone: much of it is 200-400 feet high. It extends from the shores of County Dublin across the country to Galway Bay and Clew Bay. Everywhere except in a belt of lowland extending north and south from Galway Bay, these limestones are covered with glacial drifts: this driftless area includes some remarkable limestone pavements.

In the northeast the Triassic, Liassic, and Cretaceous beds were laid down, but they are exposed at the surface only in a few places, notably the Lagan Valley. Elsewhere they are covered with basalts, poured out in Tertiary times in a series of flows 15-20 feet thick and covering in all some 1,500 square miles. From the Antrim coast road to the north of Belfast, it is possible to see the Cretaceous chalks, Liassic clays, red Triassic marls, and sandstones beneath the cover of basalts: blocks of basalt have slipped from the escarpment over the underlying strata. This northeastern area consists of plateaus and wide low-

lands: the edge of the plateau is clearly seen in Cave Hill and Divis, immediately to the west of Belfast and in the plateau of County Antrim farther north, but in the lower Bann Valley basalts underlie lowlands. The most spectacular outcrop of the basalts is the Giant's Causeway, County Antrim, where hexagonal basalts are exposed on the coast: here it is possible to walk for several miles beside a remarkable series of cliffs, which have a lower layer of regular, hexagonal columns and an upper layer of thin irregular prisms molded into fantastic shapes and called by such names as the Giant's Organ.

The last—and in many ways the most important—phase in the geological history of Ireland was its glaciation. Two main icesheets left limestone-bearing drift over large parts of the Central Lowland: in the northeast the drifts are derived partly from Scottish sources and also include some basalt and chalks of local origin. There were also various mountain glaciations, some of small extent but leaving (for example, in the Comeraghs and the Reeks of Kerry) a number of wonderful corrie basins. Other mountain glaciations were larger: those of the Wicklow Mountains, for example, carried ice far from the center of the hills, and an even greater ice-sheet which covered the mountains of Kerry and western Cork extended to the eastern limit of County Cork; the drifts are largely sand and gravel. A few small areas of Ireland were apparently never covered by ice, but almost everywhere else the soils and surface drainage are affected by the glaciation.

Glaciation has affected the physical geography of Ireland in various ways. In parts of the west, notably in Connemara (the area west of Galway), the ice apparently removed the soil and left bare rock surfaces—much as it did in parts of Canada or of Finland—but over most of the lowland there is an accumulation of drift, molded into drumlins in a wide belt of country extending from Belfast Lough and the neighborhood of Dundalk westwards to Donegal, Sligo, and Clew bays; and there are also isolated swarms in the lower Bann Valley, various lowlands of north and west Donegal, and, far to the south, in Bantry Bay. Drumlins, it has been estimated, cover one eighth of the surface of Ireland: some are of considerable size, even as much as a mile long, but many are 400-500 yards long and half as broad. These "little hills" are generally 50-100 feet high—but only a few of them have been penetrated by cuttings and some may have a rock core. Normally the true "drumlin" is thought to consist entirely of drift, but many hills that look like drumlins may be due to the deposition of drift on a rock surface.

As the last icesheet decayed, vast quantities of water were liberated and the surface drainage of the country was restored. Meltwaters formed some remarkable channels in and around various uplands: in the Wicklow Mountains, for example, there are over 100 meltwater channels, some quite small but others hundreds of feet deep though now occupied only by small "misfit" streams. In this case ice on either side of the mountains prevented the escape of meltwater to the east or west, and so channels were cut in a north-south direction, parallel to the trend of the mountains. And the channels of other ranges, such as the Mourne, the Carlingford, and the Sperrins, are almost as spectacular. It is, however, the eskers of the lowlands that have excited the greatest curiosity. These are long sinuous ridges stand-

ing at least 20-30 feet above the surrounding countryside; they exist in east-west and in north-south lines across the central lowland. Their origin has been ascribed to deposition of gravel and sand in streams beneath the icesheet, to the formation of deltas in standing water at the margin of an icesheet, and to various other causes. They are interesting features of the Irish central lowland; in some places they are surrounded by peat bogs.

Soils.—As yet, there has been comparatively little soil analysis in Ireland, though the importance of this subject in an agricultural country was recognized as long ago as 1907, when J. R. Kilroe published his *Soil Geology of Ireland*. He showed that most of the Irish soils originate from drifts and were varied in quality, here sandy and there clayed: where drifts did not occur, some of the older rocks, such as quartzites, certain granites, and shales, weathered into infertile soils left uncultivated, though the patches of drift upon them were used for farmland. Equally, some of the bare limestone country of County Clare and County Galway is valueless for agriculture, but where these limestones have weathered into soil, a nutritive herbage develops which forms admirable pasture for sheep and cattle.

Study of drainage will provide one key to the qualities of Irish soils. Over most of the country, rainfalls are high (see below) and therefore soils retentive of moisture, such as clays, are frequently waterlogged, especially in low-lying areas. On a slope with good natural drainage, even a heavy clay soil will be suited to cultivation: in a depression, it may be a marsh, thickly covered with reeds and even wild iris but having a certain value as a pasture. Such soils are markedly acid, and therefore the fertilizers used include lime and various phosphates, partly in order to give some alkaline content. Lighter soils, such as sands, are less frequent in Ireland, though they include the famous Curragh area near Kildare, an open sheepwalk on glacial sands covering nine square miles. The eskers of the lowland normally consist of gravels and sands, generally of such low fertility that they are left uncultivated as lines of heath or woodland; but light soils are comparatively rare and the prevalence of clayey drift, containing some lime, may partly explain why so large an area of farmland is left as pasture.

Clearing of the lowland bogs of Ireland has been regarded for more than a century as one way of adding vast tracts of agricultural land for the use of the farming community. The lowland bogs vary in size from a few square yards to many square miles: the largest single expanse is the Bog of Allen, near Kildare and Edenderry. It is thought that lowland bogs develop on a fen in areas of impeded drainage, that after the Ice Age large areas between the drifts were covered with water, and that here, in time, marshy fens developed. Under the conditions of heavy rainfall, decaying vegetation was built up into a peat bog, spongy in texture, with acid water permeating the steadily increasing layers of vegetable matter. These conditions have prevailed from about 750 B.C. (the sub-Atlantic period), when the climate became moister than in the previous climatic phase (the sub-Boreal period, about 2500-750 B.C.): in this earlier period the fens developed and trees grew so plentifully that they are frequently seen when bogs are cleared. Ad-

vocates of bog clearing to provide new farmland on the underlying fen soils perhaps forget that under the present climatic conditions they would need a highly elaborate drainage to provide rich fields for crops, though cleared bogs are commonly used for potato growing and some good yields are obtained.

Climate.—What is generally called the "West Maritime" type of climate is excellently developed in Ireland. Lying to the west of Britain, it is traversed by numerous depressions from the Atlantic, all of a rain-bearing character. Cold anticyclones of continental origin in winter are less frequent than in Britain, and warm anticyclones of tropical origin are less marked in summer than in the south of England. As a whole, the climate may be described as "mild, moist, and changeable"; extreme cold, long frosts, heavy snows in winter and scorching days in summer are regarded as exceptions to the normal routine, in which one season grades imperceptibly into the next with rain as the only common element through the year. Late frosts and snows have been recorded in May, as in Britain; and every year contains some exceptional weather conditions.

Averages of temperature show a clear difference in winter between the west and east of Ireland. The mean monthly temperatures for winter in the west are 44°-45°F. (December to March), but slightly less in County Donegal, and in the east 41°-43°F. (November to March). The south coast is similar to the west, and the northwest to the east. On all the coasts, the temperatures are slightly higher than those inland at this season, and warm soft breezes, not infrequently accompanied by mist and rain, are characteristic. In summer, the isotherms show a steady decrease of temperature from south to north, from 60°-61°F. in Cork to 57°F. on the coasts of County Donegal. The evergreen quality of vegetation in the west is thought to be due to the lack of any marked check to plant growth through either cold or lack of rain; the arbutus, for example, a Mediterranean plant, is a low shrub in its own home but a tree in Ireland.

Rainfall in Ireland is, by general consent, excessive, and some four fifths of the country has 30-50 inches, whereas a similar proportion of England has 20-30 inches. Only some 500 square miles, in County Dublin and County Meath, has less than 30 inches, and in the mountains there are annual averages of 50-100 inches. Relief rain figures prominently in the west, and the highest falls, 90-100 inches, are recorded from Kerry, western Mayo, and western Galway (for example, Gap of Dunloe, Killarney, 94 inches). There are also heavy falls at some of the western lowland stations near the mountains, such as Garinish Island, Bantry, County Cork, 70 inches, and Kenmare, 65 inches. The number of rain days (that is, when more than 0.01 inch falls within 24 hours) is high everywhere, and varies from 175 in the extreme southeast to 200-250 on the west coast, and even more in the western mountains: at Cahersiveen, County Kerry, the rainfall of 56 inches falls on 252 days and in 834 hours, twice as many as in London. In the west, there is a marked winter maximum of rainfall; but in the east, a more even distribution. Dublin has its highest monthly fall in August, due to occasional thunderstorms or very heavy depression rains.

Westerly winds predominate in Ireland, though

IRELAND

The famous, timeworn Cross of Cashel (8th century),
County Tipperary.

The Round Tower on the rock of Cashel, near Tipperary.

The ruins of Ross Castle, Kerry County.

naturally a country subject to so many depressions has winds from all quarters: but at most stations for which detailed records exist, nearly two thirds of the winds come from some direction between south and northwest. Winds of gale force average 40 a year on the west coast, and several winds of more than 90 miles per hour have been recorded. On Jan. 30, 1925, a train was blown off a viaduct in County Donegal and most of the passengers killed or injured. The light railways take special precautions against gales; for example, the West Clare Railway authorities ballast the carriages with concrete when the winds reach 60 miles per hour, and traffic ceases when the winds reach 80 miles per hour.

The climate has a direct effect on the vegetation, described below. It cannot be too strongly stressed that the figures used in this section are averages and that the weather varies considerably from one season to another. For Queen's University, Belfast, figures for 79 years (1861-1939) are available: the average rainfall was 34.9 inches, but this occurred in only two years, though most years had within 15 per cent of the average. A few, however, had as much as 25 per cent more or less than the average, and it seems that a period of dry years is followed by a period of wet years.

Flora and Fauna.—Ireland is poorer in flora than Britain: it is estimated to have only two thirds as many species of plants as its neighbor, due to the fact that Ireland was separated from Britain before Britain was separated from continental Europe. Much of the Irish flora must have survived the Ice Age either on the ice-free strips within the country or on unglaciated areas now submerged. There are some species of American origin, which are presumed to have reached Ireland and Greenland, and others are of Mediterranean origin: these are found largely but not exclusively, on the west coasts, in some places intermingled with one another and in others among plants of European origin.

The American species include an orchid (*Spiranthes stricta*), found in damp meadows and in the Bann Valley, and a rush (*Juncus macer*) which has been discovered in County Wicklow and also in the extreme southwest. None of the American species is conspicuous, and more interest lies in the consideration of Mediterranean plants, which include the arbutus (see above) growing into a tree, various ericas (heaths), and various saxifrages. The wealth and variety of saxifrages in the west of Ireland has attracted many botanists: one, *Saxifraga spathularis*, which grows in Portugal, northern Spain, and the Pyrenees, is luxuriantly developed in mountain areas of Kerry, Cork, Galway, and Mayo. Alpine plants have a poor range of species, and although the mountains have wide heathery moorlands, there is no continuous area of land at a sufficient altitude to possess an arctic-alpine vegetation similar to that of the English Lake District, Snowdonia (North Wales), or the Scottish Highlands. Alpines are more frequent in the north than the south, though in Ireland, as in the west of Scotland, they occur at all altitudes down to sea level. In all probability, the remarkable spread of alpine plants in the west is due to indirect climatic influence: the restriction of tree growth by seawinds has left land available for other plants. Consequently, there are some strange mixtures of plants in the west, notably in the Burren of County Clare, which has the alpine species *Dryas octo-*

petala and *Gentiana verna* mingled with the Mediterranean maidenhair fern (*Adiantum capillus-veneris*): the latter is found in sheltered hollows and cracks in the limestone pavement. The restriction of vegetation to ground species characteristic of the west coast is a feature shared by the similar coasts of Scotland and Norway.

Only a short distance from the coast, in sheltered places, luxuriant tree growth is seen, notably in the Killarney Valley, which has rich woods in which trees are covered with ferns and mosses, and the ground flora forms a dense mat of vegetation. In exposed places the phenomenon of wind-shearing is seen: a grove of trees will have low growth on the west and higher growth on the east, and single trees will have their buds killed on the west side. In these circumstances, it is difficult to establish a treeline in terms of altitude, for on the west coast the treeline is at sea level, at 600-800 feet in Kerry, and in the east, for example in the Wicklow Mountains, it is at 1,200 feet or more, in some sheltered valleys.

At the present time, Ireland has a mere 2½ per cent of its area in woodland, less than any other European country except Iceland, but before the woods were cleared for agricultural expansion and other purposes, a large part of the land was covered with forest, though the bogs are naturally treeless. Nevertheless, Ireland has a wooded appearance, as numerous single trees are planted in hedgerows or as small sheltering woods near farmlands. The oak is the dominant tree in most woods, along with birch, or ash (this especially on limestone soils), hazel, rowan, and many more: in damp places, alders and willows are found. Hazel scrub is developed in profusion on the limestones near Galway Bay, away from the west coast. There are only two native conifers, the juniper and the yew, but various pines and larches have seeded themselves plentifully and even invaded some of the country's oakwoods and birchwoods: other introduced trees, such as the sycamore, have also spread by seeding, and in the rich moist woods of the Killarney area rhododendrons have run wild. Even the exotic bamboo will grow luxuriantly in sheltered places in the south of Ireland: the National Botanic Gardens at Glasnevin, Dublin, have a remarkable collection of trees drawn from various parts of the world.

The fauna, like the flora, has fewer species than Britain, but it includes some species with a likeness to those of Scandinavian and Arctic regions, and others with Mediterranean affinities. Of the mammals, the fox, the badger, the otter, the stoat are all abundant, but the weasel and the polecat do not exist. Wolves were exterminated by the 18th century. Hedgehogs abound, but there are no moles, and Irish visitors to Britain are puzzled by the molehills of many pastures. There are fewer types of bats in Ireland. The Irish hare is the varying hare of the Scottish highlands and various alpine and northern regions of continental Europe, but it does not normally change its coat to whiteness in winter in Ireland.

Of the birds, there are fewer species, but many sea birds exist in vast numbers on the cliffs, especially on the west coast; these include gulls and dippers. Certain birds of prey, such as the peregrine falcon, nest on seacliffs and mountains throughout the country, and the golden eagle nests in the remoter parts of Mayo and Donegal. But a number of familiar English birds, such as the nightingale, the reed warbler,

and the tawny owl, are quite unknown in Ireland: the magpie, said to have arrived in a small flock in 1684, has spread widely through the country.

The brown lizard is the only native reptile, and the absence of snakes (said by legend to have been banished by St. Patrick) is well known. The common frog is abundant, but only a single species of the three British newts is found. Some of the invertebrates show Mediterranean affinities, notably a spotted slug found in western Kerry and western Cork. A snail, *Helix pisana*, is found in the east and in Britain only in south Wales and Cornwall; it also occurs in southern France and along the Mediterranean shores. Researches on the fauna raise the same fascinating problems of origin that are raised in considering the flora: clearly there is a complex relationship between the two.

T. W. FREEMAN,

Reader in Economic Geography, University of Manchester.

HISTORY TO 1601 A.D.

Irish literature contains stories of the occupation of the island by various peoples—Nemedians, Fomorians, Fírbolgs, Tuatha De Danann, Milesians—in succession. The last-named people, called in Irish the *Clanna Míled*, has been identified generally in modern times with the Celts, who brought to Ireland a Celtic language or languages and Celtic civilization about the middle of the first millennium B.C. Ireland marked the western limit to a great movement of expansion which carried the Celts from a homeland somewhere in central Europe to Asia Minor, Spain, the Low Countries, France, and England. Beyond Galway lay the Atlantic breakers and the boundless waste of ocean on which frail barques ventured at their peril.

A glimpse of Ireland at the dawn of history is afforded by tales of the Cú Chulainn or Ulster literary cycle. The personages whose doings this cycle records would have lived about the beginning of the Christian era. By that time the island had been parceled out among five major kings, a division that was to last until the Middle Ages, when Meath would lose its ancient status and Ulster, Leinster, Munster, and Connacht become the four Irish provinces. The Finn cycle of Irish literature, which belongs perhaps to the 3d century A.D., shows no appreciable change in the Irish political situation, though it does indicate changes in civilization. Struggles for power between the five kings led to the predominance of the Meath dynasty in the northern half of Ireland (Leth Cuinn) and to the predominance of the Munster dynasty in the southern half of Ireland (Leth Moga). Finally, at a date before 400 A.D., the Meath dynasts established their claim to suzerainty over the whole of Ireland and to the

corresponding title *Ri Erend* (King of Ireland). Their chief fortress was on the hill of Tara, which thus became fixed in tradition as the capital, the home of the high-king, the symbol of national unity, the focus of national aspirations.

The first high-king of whom the historian can speak with certainty is Niall of the Nine Hostages, undoubtedly one of the greatest Irishmen who ever lived. Three of his sons won for themselves a new kingdom in northwestern Ulster; other sons were settled in strong positions in the large midland region between the Shannon and the Irish Sea. Two of his brothers were successively kings of Connacht. His son, Loeguire, was high-king when St. Patrick came as a missionary to Ireland (the traditional date is 432 A.D.). Niall's direct descendants, the Ui Neill, held the kingship of Ireland without a break from 482 to 1002. From 732 onwards this highest honor in the land went alternately to the Ui Neill of Ulster and the Ui Neill of the midlands. From Niall, too, descended the best-beloved of native Irish saints, Columba of Iona, or Colmcille, the princely families of O'Neill, O'Donnell, MacLoughlin, O Maelsechlainn, and a host of lesser families who form no small part of the population of Ireland in modern times.

Within a short time after the introduction of Christianity Ireland enjoyed a period of bloom in the realms of religion, learning, and art, to such an extent that the country could be called "The Island of Saints and Scholars." In the political order there was no comparable advance. From the beginning of the 6th century to the beginning of the 9th century society remained essentially unchanged. Individual liberty was highly prized; so also, the liberty of the family within the local state; the liberty of the small rural state within the small local kingdom; the liberty of the small local kingdom within the five larger kingdoms; the liberty of these (Ulster, Meath, Leinster, Munster, Connacht) in their relations with the king of Ireland. Though the high-king's prestige was immense, his political power outside his own patrimony was generally restricted: it depended much on personal distinction and, in the ultimate analysis, on the size of his army and the capacity which he showed when he led it into the field.

Norse Invaders.—In 795 Ireland was attacked for the first time by a dangerous foreign enemy. He came from the pagan and barbarian north (chiefly, it would seem, from Norway rather than from Denmark or Sweden) and continued his depredations for more than two centuries. This is the Norse Era in Irish history (795–1014). In the art of seamanship the Northmen then had no equals in Europe, outside of Byzantium, and they used their one accomplishment to win riches and power at the expense of other peoples. From 795 to 837 Ireland was thrown into turmoil by their raids. They came in fleets, sometimes large, sometimes small, landed suddenly in a bay or creek, despoiled the countryside (especially the peaceful monastic settlements), and returned with booty to the safety of their ships before the local state could gather its army in self-defense. In 837 they took permanent possession of a strip of land near the Liffey mouth. This is the origin of the town and later city of Dublin. Now and afterwards the Irish kings showed more eagerness to use the Norse as foils in the game of politics than to drive them once for all from the country. An unfortunate cam-

paign, in which Munster was defeated by the high-king and grievously weakened led to the foundation of the two Norse towns, Waterford and Limerick, in the south of Ireland about 920. The presence of the Northmen at Limerick led to a fierce local reaction. Surrounding the new settlers was a little state called Dal Chais. The energetic dynasts of this people waged relentless war on the intruders, building up in the process an army which in time became strong enough not merely to subdue the foreigners but to secure for its commander the kingship of Munster. Brian Boramha (Brian; Brian Boru), second Munster king of the Dalcassian line, deposed the Uí Neill monarch, Malachy II, in 1002, and took his place as king of Ireland. In a famous battle fought at Clontarf, near Dublin, in 1014, Brian was opposed not only by Irish malcontents but by the Norse of Dublin assisted by a formidable force of Norse auxiliaries from abroad. Brian's victory, won at the cost of his own life, broke forever the power of the Northmen in Ireland. In the next generation they accepted the Christian faith, after which they lived on in their own towns, under the immediate rule of their own leaders but subject to Irish kings.

Political Ferment.—An unhappy consequence of Brian Boramha's intrusion into the high-kingship was confusion at his death. On the one hand his son and successor in Munster was unable to take his brilliant father's place as king of Ireland; on the other hand, the tradition of Uí Neill succession was shattered beyond repair. Thus it happened that for half a century (1022–1072) the throne of Ireland remained empty. The principle was maintained that supreme political authority in the country should be represented by a high-king, but there was no ruler strong enough to merit recognition as such. Strife increased, not only between state and state, but also within various states and even within dynasties, a development whose deepest roots lay in the Irish system of succession to kingship. When a vacancy occurred it was filled by election. The prince chosen was one of a group, all of whom had rights that were theoretically equal. Disappointed candidates were all too prone to remain in a state of permanent conspiracy against the more fortunate rival who had been elected. This weakness in the Irish constitution had inevitably been intensified by the disintegration due to the Norse invasions.

Donnchad, son of Brian Boramha, was the chief ruler in the Ireland of his day, but his power was meager outside of Munster. Deposed by his nephew Toirdelbach in 1064, he journeyed as a pilgrim to Rome; and at his death he was buried there in the church of San Stefano Rotondo. By 1072 the prestige of Toirdelbach O'Brien had increased to the point when he could lay claim to the kingship of Ireland, but that goal was never reached during the 14 years of life that remained to him.

A greater man than Toirdelbach was his son, King Muirchertach O'Brien. He was an enthusiastic supporter of the movement for reform inaugurated by Pope Gregory VII. One of his daughters married a son of King Magnus of Norway; another daughter traveled to England to become the wife of a powerful Norman lord. Muirchertach exchanged letters with St. Anselm of Canterbury, who addressed him as "glorious King of Ireland." The title, however, was never quite justified by Muirchertach's achievement, for

away in the north, near Derry, sat a king, Domnall Mac Lochlainn, whose opposition he was unable to overcome.

Muirchertach O'Brien died in 1119, leaving his inheritance to nephews of lesser caliber. Mac Lochlainn died soon afterwards, and the chief place on the stage of Irish politics passed to the king of Connacht, Toirdelbach O'Connor. He used naval power with some effect in the Shannon River and along the Atlantic seaboard. He also built bridges at strategic points and erected fortresses of the new type, called castles, which the Norman conquerors had multiplied in England. O'Connor's success was for a time remarkable, but the promise of his early years was not fulfilled, and long before his death in 1153 his failure to reduce the other Irish states to submission was painfully evident. His successor as chief claimant to the kingship of Ireland was Muirchertach Mac Lochlainn, grandson of the Domnall mentioned above. By 1161 his ambition seemed to be realized but fortune soon deserted him, and in 1166 he lost both throne and life. The way was then open for Ruaidrí O'Connor, son of Toirdelbach, to win recognition as king of Ireland. In that capacity he presided over the great national assembly at Tailtiu in Meath in 1168. The days of struggle for the high-kingship seemed to be over and the throne of Ireland firmly in the keeping of the royal house of Connacht.

Anglo-Norman Penetration.—Peace, however, was a gift which the people of Ireland were not destined to enjoy. O'Connor, in the first major action of his rule as high-king, expelled Diarmaid Mac Murchadha from the kingship of Leinster. The deposed ruler crossed the Irish Sea and sought help from Henry II of England. Henry had already contemplated the conquest of Ireland, for we have it on the word of John of Salisbury that in 1154 he had sought sanction for the step from the English-born Pope Adrian IV. Thus the appeal of Mac Murchadha provided a happy excuse for the furtherance of his policy. The English king espoused enthusiastically the exile's cause. Small contingents of Norman knights were sent to Ireland with Mac Murchadha, but were easily defeated by the high-king. Then, in August 1170, came an army of picked men under a redoubtable leader, Richard de Clare, 2d earl of Pembroke, better known as Strongbow. O'Connor and his troops found themselves confronted by a situation with which they were unable to cope: the Norman knights were clad in armor from head to foot; they carried long lances and fought from horseback; and they were assisted by archers armed with longbow and crossbow. Moreover, they had the rigid discipline of professional soldiers, and they were skilled in erecting fortifications which the Irish lacked instruments to reduce. In a word, the Normans were incomparably superior to the Irish of the day in military organization.

The inevitable result followed. Waterford fell, and also Dublin. When Mac Murchadha died, Strongbow, who had married his daughter, claimed the succession to Leinster. O'Connor besieged Dublin, but without success. Henry II himself arrived in Ireland in October 1171, and stayed until Easter 1172. O'Connor and the Irish princes submitted to the Norman king on the understanding that this would save them from the depredations of the barons. But in this they were mistaken; large areas of Irish land

were parceled out to the nominees of the crown. After three years of warfare a treaty was signed at Windsor between O'Connor and Henry II, but its terms were violated by Henry and the Norman lords, and the struggle continued.

For over a century the tide of fortune favored the Norman invaders, who carved out for themselves principalities in all parts of Ireland. Henry II sent his son, Prince John, to govern the conquered island in 1185. When John became king of England he built a strong castle at Dublin and arranged to have the country administered by a central government. An attempt was made to fill the bishoprics and higher offices of the Church with Anglo-Norman prelates. The 13th century saw not only the conquest of Coniacht but the rise to eminence of the two great Fitzgerald families of Kildare and Desmond and the families of De Burgh (Burke) and Butler.

By 1300 Norman power had passed its peak and an Irish recovery had begun. After the victory of Bannockburn (June 1314), Robert Bruce got in touch with the Irish princes and encouraged their efforts to form a national league. His brother, Edward Bruce, was crowned king of Ireland on May Day, 1316, but in a battle near Dundalk (October 1318), Bruce was killed and the Norman colony saved. During the long campaign English organization weakened and the Irish began to advance steadily in every portion of the island.

Assimilation of the Normans.—Remarkable in the 14th century is the extent to which the Normans became assimilated. In the case of the great lords the change was partial, for though they adopted Irish civilization, they did not renounce their allegiance to the English crown. By 1366 the colony had become so "degenerate" that Lionel, son of Edward III, was sent from England to provide a remedy. The "Statutes of Kilkenny" which he promulgated sought to preserve the English way of life in that part of Ireland which the colonists still controlled. The Statutes were a dead letter, and before the century ended the government in Dublin was compelled to pay "black rent" to Mac Murchadha of Leinster to restrain him from attacking the capital. Visits of Richard II in 1394 and again in 1399 ended in utter failure.

In the 15th century the picture remains essentially the same. During this period the Fitzgeralds in Desmond and Kildare reached the zenith of their power. Gerald, the "Great Earl" of Kildare (1477-1513), held the office of deputy (viceroys) for 30 years and ruled Ireland like a king. But the old order was changing with the accession to the throne of England of highly autocratic Tudor sovereigns.

Tudor Period.—Gerald, son of "the Great Earl," and himself 9th earl of Kildare, was appointed lord deputy by Henry VIII. Wolsey, however, hated the Fitzgeralds and was resolved to bring about their downfall. Kildare survived unscathed until 1533. Summoned to London then to answer charges, he named his son, "Silken Thomas," deputy in his stead. A report soon reached Ireland that the earl had been executed. Thomas immediately rebelled. In the campaign which followed he was defeated and forced to surrender; and he and his five uncles were beheaded in the Tower of London in 1537. With them the house of Kildare, as an independent force in Irish politics, came to an end.

The break of Henry VIII with Pope Clement VII had of necessity repercussions in Ireland. Henry had carried through the Irish Parliament acts that gave him complete control of ecclesiastical affairs. All monasteries were suppressed, save such as for the moment lay outside the reach of Henry's arm. Tudor power in the political field was now overwhelming, and the Irish princes tried to counteract it by securing aid from Henry II of France, but the negotiations came to nothing.

Queen Mary Tudor initiated the policy of expelling native Irish from their holdings and introducing in their stead planters from England. The idea appealed also to her successor, Elizabeth, and was applied by her with effect in Munster towards the end of her reign, when a favorable opportunity offered.

Elizabeth's policy in Ireland, like that of Henry VIII, was based on two main principles: complete control of the whole country by means of government officials operating from Dublin, and complete uniformity in religion. This meant constant warfare, since the Irish were prepared to fight to the death for their freedom and for their Catholic faith. In Ulster, where the old Irish population had been least disturbed, the opposition was strongest. Shane O'Neill ruled the northern province for years like a king. When not at peace with Elizabeth and her deputies he fought them with considerable success. His own overbearing rule was, however, resented by Ulster chiefs and in a quarrel with the MacDonnells of Antrim he was slain in 1567.

Soon afterwards a confederacy of Irishmen was formed under the leadership of the Desmond nobleman, James Fitzmaurice Fitzgerald. The Irish princes and lords, hamstrung in their effort to make war by the lack of guns and ammunition, appealed to Philip II of Spain for help. Philip dallied, as always. The religious issue was now uppermost and the papal court, no less than the court of the Spanish king, was interested in the result. Small expeditions were fitted out and sent to Ireland, but they were annihilated by the English commanders. Sir James was killed (1579). Gerald Fitzgerald, the 15th earl of Desmond, lacked energy and ability as a leader. So the movement collapsed; Desmond was beheaded (1583) and his great estates in Munster divided into plots and disposed of to English planters.

Within a few years, however, resistance was renewed on a national scale. The leaders were Hugh O'Neill, earl of Tyrone (since 1585) and Hugh O'Donnell of Tyrconnell or Donegal. O'Neill had been taken to England as a boy and educated in English ways. O'Donnell had twice been captured and twice escaped from Dublin Castle; with his second and successful bid for freedom, on Christmas Eve 1591, the Nine Years' War may be said to begin.

Nine Years' War.—Not only did all attacks on the north by English armies fail, but in 1598 O'Neill won an important victory over the English commander, Marshal Bagenal, at the Yellow Ford, near Armagh. The result was a great increase of enthusiasm and a gathering of forces from all Ireland under O'Neill's standard. Elizabeth was alarmed. A new army of immense size was collected and sent to Ireland under the command of Robert Devereux, 2d earl of Essex, but it achieved nothing and the campaign ended in a truce and the drafting by O'Neill of conditions under which he was willing to make

peace. These were rejected by Elizabeth; and Essex, after a foolish revolt, lost his head. His place was taken by Lord Mountjoy, who adopted the ruthless policy of burning all crops and all food and so reducing the people to submission by famine rather than by arms. O'Neill had appealed to Spain for help, above all for artillery, without which his army could not maintain itself in the field. Philip III at last (September 1601) sent a small contingent of men and arms, but it landed at Kinsale in the south, where it could give only the minimum of assistance to O'Neill. Soon the Spaniards were shut in by the English fleet at the harbor mouth and by Mountjoy's army on the land side round the walls. O'Neill and O'Donnell marched from the north to the Spaniards' relief. It was decided, against O'Neill's better judgment, to undertake a general assault on the English lines. This took place on Dec. 23, 1601, and completely miscarried. The Battle of Kinsale proved to be a defeat from which O'Neill and O'Donnell were unable to recover. They were compelled to sue for peace and to accept the conditions which the English were willing to offer.

JOHN RYAN, S. J.

HISTORY FROM 1601 TO 1800

The Battle of Kinsale proved to be decisive: the prospect of an independent Irish nation, based on the old Gaelic order, was quickly to disappear. Hugh O'Neill held out in Ulster until 1603, when he made his submission to the lord deputy, Mountjoy, only to find that Queen Elizabeth had died a week before. With the new king, James I, O'Neill had been on friendly terms: had he delayed his submission, he might at least have been spared some indignities. Mountjoy, however, was not vindictive, and with James disposed to leniency the reign opened promisingly enough for Ireland. The promise was not maintained. Alarmed by the Gunpowder Plot (q.v.) and unable to stem the anti-popery tide in England, James had little power, even had he the will, to prevent measures against the Irish Catholics. Those measures soon extended beyond the enactment of laws enjoining conformity with the Established Church. Under the lord deputyship of Sir Arthur Chichester (1604-1614) the ground was prepared for the Penal Laws under which Irish Catholics were to labor for more than two centuries. Catholics were *ipso facto* suspected rebels; and from this uncongenial atmosphere O'Neill, O'Donnell, and others of the "Old Irish" decided to take refuge in exile. "The Flight of the Earls" in 1607 symbolized the collapse of the Old Irish society; and it was made the excuse for the most comprehensive confiscation and resettlement of land that had yet been effected. Half a million acres in Ulster were distributed to settlers from across the channel, mainly Presbyterians from the Scottish Lowlands. The natives, though not expelled outright, found themselves left in possession only of land that was too poor in quality to be an attraction to the newcomers.

To confirm all the measures taken in the early part of his reign, James called a parliament in Dublin in 1613. With some skill, this assembly was "packed" to ensure a Protestant majority. The loyalty of the minority of Catholic representatives was not in question, but it was determined that they should have no opportunity to make use of the occasion to attack

the Penal Laws. They were nevertheless strong enough, if not to secure a much greater degree of toleration, at least to ensure that no further steps were taken against them, and in 1615, James, finding that little was to be obtained from the parliament, ordered its dissolution.

In the last years of James's reign Ireland was tranquil, and comparatively prosperous; and the accession of Charles I, who had married a Catholic and was himself "High Church," gave promise of still brighter days to come. Charles, however, regarded Ireland throughout his reign primarily as a potential source of revenue, to be obtained if necessary by double-dealing. Concessions to the Catholics were offered for cash; the money was paid over, but the Graces (as these concessions were termed) were never given statutory effect. No real departure, in fact, was made from the Irish policy of James until, in 1632, Thomas Wentworth arrived as lord deputy, determined to make Ireland a source both of wealth and of strength to the crown. Roman Catholic and Protestant were played off, one against the other, to keep them occupied while Wentworth strove to restore the royal prerogatives and powers—and the revenues attached to them—that had fallen into the hands of local magnates. Many of his reforms were salutary, but they brought him the undying hatred of the monopolists—men such as Richard Boyle, earl of Cork who as a young man had arrived in Ireland a penniless adventurer and risen to be the greatest power in the land. Wentworth, made earl of Strafford in 1640, had been recalled in 1639 to deal with Charles's increasing difficulties at home; and it was largely the evidence of the men he had angered in Ireland that helped, two years later, to bring him to the block.

Insurrection.—In the meantime, the government of Ireland had fallen into the hands of supporters of the Puritan Parliament of England, whose actions helped to precipitate a rebellion in 1641 in which the natives rose and massacred the Ulster settlers. The insurrection was an outburst against repression, rather than a calculated nationalist uprising; and the issues were confused by the fact that Charles, who originally attempted to put down the rebels, was soon in need of their assistance against his Parliamentary foes. The Irish Catholics formed a confederacy, calling back from the continent the exiles Owen Roe O'Neill and Gen. Thomas Preston to lead their forces. Owen, a nephew of Hugh O'Neill, was the natural leader of the Old Irish stock; Preston, of the Catholic Old English. In addition there was the Anglican James Butler, marquiss of Ormonde, Charles's lord lieutenant in Ireland, at the head of the Royalist forces. Ormonde, at first ordered to put down the rebels, was soon required by Charles to come to terms with them, to secure their help against the Parliamentary forces. Between these groups divisions were inevitable, serious enough to enable the Parliamentary forces, numerically far weaker, to survive. Not even Owen Roe's resounding victory at Benburb in 1646 succeeded in dislodging them, and antagonism between the Royalists and the Catholics paved the way both for Charles's final defeat and for Oliver Cromwell's subjugation of Ireland. Cromwell arrived in Ireland in 1649, promptly avenging the deaths of the Ulster settlers in his massacres of the inhabitants of Drogheda and Wexford. The combination of terrorism and military skill led to the

collapse of the rebellion, though it was not finally stamped out until 1652.

Cromwellian Regime.—"Cromwell's Curse" was not to be forgotten or forgiven in Ireland. Not only were the Irish defeated in the field; all their estates east of the Shannon were forfeited. Over half of the land to the east of the river was confiscated and redistributed in a resettlement by contrast with which the Plantation of Ulster 40 years earlier was unsystematic and naïve. Some 30,000 Irish soldiers were allowed to go into exile in the service of continental powers, and thousands of commoners were sent to virtual slavery in the West Indies. The power of the Old English in Ireland went the way of the power of the Old Irish: henceforth for generations the new English element dominated the country's life. A union with Britain was enacted in 1653, providing for Irish representation in the English Parliament; and only the short duration of Cromwellian rule prevented Ireland from effective anglicization.

The Restoration in 1660 did not entirely redress the balance, as Charles II was unwilling to risk unpopularity by concessions to the Irish Catholics. The Irish Parliament was restored, but Catholics were no longer allowed to take seats in it. Although some of the Catholic lands were regained by their former owners, the Protestant "ascendancy" remained firmly established, and such toleration as the Catholics were able to obtain in practice was only on sufferance. The Anglican Church alone was officially recognized. Again, a period of peace under the able rule of Ormonde, who was lord lieutenant for the greater part of the reign, brought a revival in prosperity; and at Charles II's death in 1685 the country was in a fair way to recovery from the chaos of the 1640's. But the brief rule of his successor, James II, brought with it disaster. The appointment of a Catholic, Richard Talbot, earl of Tyrconnell, as commander in chief and then as lord deputy, led to a revival of the hopes that had given rise to the Catholic Confederacy. Some political power was restored to Catholic hands, and when William of Orange drove James from England in 1688, the Irish gave James their loyalty as the legitimate king. James had no sympathy with Irish national aspirations, but he saw in these loyal subjects a weapon which he could use to procure his restoration. Louis XIV of France thought to use the Irish in pursuance of his wider aims, and in 1689 he dispatched James in a French fleet to Kinsale. Once again, the divided and sometimes conflicting motives of the Irish helped to paralyze their effort. The greater experience and skill of William's forces led to the crushing defeat of the Irish at the Battle of the Boyne in 1690, and the following year, the last of their commanders, Patrick Sarsfield, surrendered at Limerick and was allowed to depart with most of his men to fight for France, as the "Wild Geese," on continental fields.

Penal Laws Maintained.—If the settlement made by William III was less repressive than Cromwell's, the reason was that there was not so much to repress. In the event, however, the new reign bore more heavily on the Irish because the Penal Laws were not relaxed, as they had been on similar occasions under the Stuarts, as soon as a state of emergency no longer existed. The Penal Laws remained, and were actually intensified, although this was a flagrant breach of

the treaty made at Limerick. Under them, the Catholics sank into the condition of helots. Legally designated "Papists," they found the doors to the acquisition of land, to education, and to administrative posts closed to them. Their decline was facilitated by the introduction of the potato, which provided a food upon which peasant families could live on the minimum of land, assisting the Catholic peasantry to sink into a squalor and misery as abject as was to be found anywhere in Europe.

The Protestant "ascendancy," however, soon found themselves unable to profit from the subjection of their fellow countrymen. Even if the Irish Parliament had not been in effect manipulated by the English executive, it was in any case severely restricted in its competence. Ireland was to all intents subject to British rule. In commerce, this was particularly galling. The industry of the country was virtually annihilated by English legislation at the behest of English traders, jealous of potential rivals; and only linen, among Irish manufactures, continued to enjoy prosperity.

Under Queen Anne the Penal Laws became yet more rigorous; for example, a gavelkind (land tenure) act was passed ruling that land owned by Catholics must be divided up amongst all the owners' heirs, unless the eldest should become a convert to the Established Church, in which case all the property would be his. The Irish had not brought this further burden upon themselves, crushed and dispirited as they were. It was their misfortune that the Stuart pretenders to the British throne continued to act as a threat to the safety of the House of Orange, and then of the Hanoverian dynasty, giving repression its justification.

The first half of the 18th century would be black indeed, were it not illumined for a brief spell by the genius of Jonathan Swift. He appeared on the scene at a time when his country's commerce was nearly extinguished, its religion vindictively penalized, and its government in alien hands. The viceroys rarely felt it necessary even to visit the country under their charge, and the land was ruled by lords justices, who transacted such routine business as was required with the help of a Parliament well "packed" with placemen—the "undertakers," as they came to be called. Most of the lucrative posts went to Englishmen. In 1719 the Declaratory Act finally removed what little substance of Irish legislative independence remained, affirming the right of the English Parliament to bind Ireland in its acts; and only the shadow—the corrupt Irish Parliament—remained. So confident were the English of their strength in Ireland that a project put forward in 1722 that would have led to a debasement of the Irish coinage for the profit of William Wood, a protégé of one of George I's former mistresses, was casually accepted. In his *Drapier's Letters*, Dean Swift, a Protestant, unleashed all the resources of his devastating invective against "Wood's halfpence." The effect was electrifying. For the first time, the Protestants were united for the Irish cause in a national issue. They roused themselves to such good purpose that the coins never made their appearance, and the English had hastily to dispatch a viceroy of some ability, Lord Carteret, to the scene.

Now that there was so little to fear from the Catholics, crushed as they were beneath the

Penal Laws, Irish Protestant nationalism began sporadically to assert itself against the irritations and humiliations of alien rule. Thus it came about that, although the Stuart rising of 1745 had little impact upon Ireland, before the turn of the half century Charles Lucas, by his political pamphlets, had gone some way towards reviving the popular feeling that *Drapier's Letters* had aroused in Dublin. A section of the Irish Parliament, too, was bestirring itself to make a demand for greater control of the national finances, and in 1753 the Commons actually threw out a money bill that had been sent over from England. Pensions and titles were hurriedly distributed to win over the dissidents. For a few years an uneasy quiet was restored; but during the viceroyalty of Lord Townshend the system of government by "undertakers" received further shocks. Townshend arrived in 1767; the following year an act was passed limiting the duration of parliaments to eight years, and in 1769 the Commons again rejected an English money bill.

Patriot Movement.—This time the attempt to bring the Irish Parliament under control was less successful. A new generation of Irish Protestants was springing up, including such men as Henry Grattan and Henry Flood, who had strong links with the Whig reformers in Britain. A Patriot Party began to grow, demanding an Irish Parliament emptied of "undertakers," with power to control the country's finance and commerce. The American War of Independence came fortuitously to their assistance. Anxious for Irish help, which was freely given, the British government felt it expedient to make certain trade concessions to Ireland, and to conciliate the Catholics, in case they should be tempted to join forces with the Patriots. Relief acts removed some of the worst of the Penal Laws. But the vital step was taken when the offer of the Patriot Party to raise a volunteer force for the defense of Ireland, against a threatened French invasion, was accepted. The Volunteers, a predominantly Protestant body led by the duke of Leinster in the south and the earl of Charlemont in the north, became first a fashionable and then a formidable force; and when their moral support was ranged behind the Patriots in their campaign to secure reform, the British government had to be told that the movement had become too strong to be resisted. The disasters in America had driven Lord North from office in Britain; and the new Whig government sent the duke of Portland to Ireland as lord lieutenant, prepared to concede parliamentary independence. The Declaratory Act was repealed, and in May 1782 Ireland, in Grattan's words, became a nation.

Or so it seemed, to judge by the popular rejoicing. But very quickly, certain weaknesses in the new constitution were revealed. Legislative independence might have been established in theory, but the practical limitations to effective self-government remained formidable. The lord lieutenant and his secretaries of state, in whose hands lay the executive power, were English nominees. Had the legislature been more representative and independent it could, by withholding supplies, have bound the executive to its will; but the majority of the seats in the Commons were controlled by a few powerful landowners, whose adhesion to the executive proved to be easily purchasable by pensions and promises of titles, honors, and awards. The judiciary were

likewise dependent upon "the Castle"—the seat in Dublin of the Irish executive—for their advancement.

Party Strife.—No sooner had independence been gained than the Patriot Party suffered from a split which materially lessened its chance to reform the constitution that it had just won. Flood and Grattan quarreled, giving the Castle the opportunity to consolidate its hold upon the Commons; the Volunteer movement lost its impetus, and the Patriots their power. By 1784 the Irish Commons were scarcely less under the executive's thumb than they had been earlier in the century.

The venality of Parliament did not, however, prevent the enactment of commercial regulations that did much to revive Irish prosperity. The Corn Law brought in by the Irish chancellor of the exchequer, John Foster, was to make Ireland one of England's chief granaries for the next half a century. In 1785 the agreement of William Pitt, who had become prime minister in Britain, was obtained to some commercial propositions that would, if carried, have put the two countries on almost equal trading terms. The propositions passed through the Irish Parliament, but English commercial interests, their fear of Irish competition aroused, procured such substantial amendments that the bill became unacceptable to the Irish legislature, and had to be withdrawn. That so much British opposition had been aroused was, however, in itself a tribute to the growing commercial vitality of the Irish nation that characterized the period.

The government's hold over the legislature was not shaken until 1789, when the possibility that the Prince of Wales, whose Whig sympathies were well known, might become regent during George III's madness, induced many members to join Grattan in supporting the prince's claims. But the king recovered his sanity; the Castle restored its majority by a lavish creation of peerages and pensions; and the rekindled hopes of the Patriots were again quenched. Thereafter the feeling began to grow in Ireland, fostered by the success of the revolutionaries in France, that constitutional changes could only be won, as they had been in 1782, by threat of force. In 1791 Wolfe Tone founded the Society of United Irishmen in Belfast, where the nucleus of the organization was provided by the northern dissenters, still sufferers to only a less degree than Catholics under the Penal Laws. The society spread rapidly over the country, mainly among the Protestant middle class. At the same time, the Catholic movement showed signs of revival. A deputation that laid its grievances before George III in London was received with sufficient royal favor to secure a further measure of relief, giving Catholics the vote, subject to a property qualification. They were, however, still excluded from the Parliament.

Their success encouraged the United Irishmen to press more strongly for electoral reform. The government, alarmed at hints that force might be used if peaceable methods failed, prosecuted Hamilton Rowan and others of the society's leaders in 1794. The movement was driven underground, losing its more law-abiding elements, and gradually taking on the characteristics of a conspiracy.

Rebellion.—The last chance that the electoral problem might be settled peaceably was lost when

Lord Fitzwilliam was recalled in 1795 from the viceroyalty that he had held for only a few weeks. He had come determined to carry a measure of Catholic emancipation, and had made a beginning by removing from office some of the ultra-Protestant officeholders who had installed themselves after 1782. They had powerful friends in Britain who succeeded in alarming Pitt; Fitzwilliam was replaced by Lord Camden, and the "ultras" were restored. The new lord lieutenant resolved to meet the growing revolutionary threat with coercion. A severe Insurrection Act was followed in 1796 by the suspension of habeas corpus. The United Irishmen, in their turn, were driven to more extreme measures, and in the same year two comparatively new recruits to the movement from the ranks of the aristocracy, Lord Edward Fitzgerald and Arthur O'Connor, went to the continent to seek French assistance. Wolfe Tone, who had left Ireland earlier, was before them; and he succeeded in persuading the French to send a fleet with an expeditionary force to Ireland. He himself was on one of the ships that reached Bantry Bay at Christmas, 1796, but appalling weather prevented disembarkation of the troops, and the chance was lost.

The threatened invasion made the Castle intensify the campaign of coercion. The military were given almost unlimited license to use torture, flogging, and execution to exterminate the rebel movement. Grattan and his followers, who had clung to the hope of constitutional reform, left public life in disgust, and the United Irishmen, in loose association with the Defenders, a Catholic peasant movement, laid plans for insurrection with or without French aid. The United Ireland movement, however, was riddled with spies and informers, who reported its every step to the Castle; and before the date fixed for the outbreak, every prominent leader had been captured or killed. Nevertheless, the rebellion broke out in the spring of 1798. It was disorganized and ill led, doomed to failure from the start; only in the southeast did the rebels achieve even momentary success, and within a month the rising had been suppressed. A French force that arrived too late to be of any help was quickly rounded up; Tone was captured at sea; Fitzgerald had been killed trying to escape arrest; and the other leaders were prepared to secure their lives by relating in full the movement's history in a formal confession.

Union.—The rebellion confirmed the British government in a view with which Pitt had been toying for many years: that only in a union of the two countries could their mutual safety be secured against internal and external enemies. Early in 1799 the union was proposed in the Irish Parliament. The motion was defeated. The rebuff only made the Castle the more determined. The Catholics were won over with the promise of emancipation; the Protestants were reassured by the argument that Catholics could never be more than an impotent minority in the British Parliament at Westminster. Such propaganda still proving insufficient, large-scale purchase was resorted to. Lord Castlereagh was employed systematically and cynically to buy out enough opponents of the measure with places, pensions, and titles, to insure a majority. In 1800, in spite of a last eloquent appeal from Grattan, the Irish Parliament signed its own death warrant by passing the Act of Union; and

the nation that he had helped to create relinquished, for over a century, its nationhood.

BRIAN INGLIS.

HISTORY FROM 1800 TO 1922

Although the Act of Union in 1800 extinguished the Irish Parliament and transferred all legislative power to London, there had been hopes of relief from the oppression which had been exerted for years by the Protestant "ascendancy" in Ireland. William Pitt had gained much Catholic support for the Union by promising that it would be at once followed by the admission of Catholics to Parliament. Catholics had been entitled to vote in the Irish elections since 1793, and it was assumed that they would soon elect Catholic members and assert their rights. But George III vetoed Catholic emancipation, and Irish questions were left entirely in the hands of the ascendancy executive in Dublin Castle. An insurrection in Dublin headed by Robert Emmet in 1803 was easily suppressed; and the following years brought a steady decline of Irish industry and trade.

Such protection of Irish interests as had been provided by the Irish Parliament was now withdrawn. Dublin ceased to be the center of social and political life, and even those landowners who continued to sit in Parliament now attended in London instead of Dublin. Many more left Ireland entirely and became absentee landlords, exacting all that they could in rents, through middlemen who found during the Napoleonic wars that it was most profitable to divide estates into small holdings, at extortionate rents which could be paid while agricultural prices were high. This increase of small holdings, combined with complete neglect by the landlords to make any improvements, produced an appalling standard of living and of housing. Young laborers could become tenants of a few acres and build a wretched hovel, equal to anything that could be got later in life; and they married in great numbers, so that the population grew with abnormal rapidity for the next 40 years.

While poverty increased among the people, a new Catholic middle class was slowly arising since the relaxation of the anti-Catholic laws. They had been excluded for generations from owning land, or even from practicing certain trades, and all the professions. But many of them had become prosperous through trade with France and other countries, and their sons could now become lawyers or doctors, though they could not enter public life.

Catholic Emancipation.—The new generation found a leader in the Catholic barrister, Daniel O'Connell, who devised means of conducting an agitation for Catholic rights within the law. By insisting on the right to petition Parliament, and by using the courts as a platform when he defended in political prosecutions, he aroused such a formidable agitation that in 1815 he could have won the admission of Catholics to Parliament, if he had accepted the proposed British veto on the appointment of Irish bishops. But he refused all such terms, and allowed the agitation to subside until 1823, when he founded the Catholic Association on a broad democratic basis, with a vast membership subscribing a penny a month. All Catholic Ireland supported his popular agita-

tion, and in 1828 he was elected for County Clare as a Catholic candidate who would not take his seat until the oath against the Catholic religion was abolished. The duke of Wellington, British prime minister, feared civil war, and in 1829, by threatening resignation, he compelled George IV to sign the Catholic Emancipation Act.

Catholics could now be elected to the British Parliament, but the Protestant ascendancy still owned most of the land and its wealth, and had a complete monopoly of power. But experience showed that without a national legislature, there was no hope of economic and social reforms. O'Connell abandoned his legal career to become the leader of a national movement for repeal of the Act of Union. His attempts to continue political agitation on the former lines were suppressed by the Whig ministry which was elected in 1831 to carry parliamentary reform in Britain, and for ten years O'Connell gave the Whigs a chance to fulfill their promises to improve Irish conditions. But in 1840 he decided to revive the popular agitation, by his old method of collecting small subscriptions from the people.

After a discouraging start, he found new support from a group of young men who founded the *Nation* newspaper in October 1842. They were led by Charles Gavan Duffy and Thomas Davis, who preached national recovery by promoting economic and cultural as well as political life. With their help, in 1843, a series of "monster meetings" was organized all over Ireland to demand repeal of the Union. The climax was to be a vast rally at Clontarf in October; but the government blocked all the approaches with troops and artillery, and O'Connell had to cancel the meeting. Soon afterwards he and all the prominent leaders were prosecuted for seditious conspiracy and imprisoned.

Potato Famine.—An appeal against their sentence succeeded unexpectedly, but when O'Connell came out of prison his health and his nerve were broken. The young men became impatient of his appeals for caution, and conflict had already arisen between him and the Young Ireland Party before Davis died suddenly in September 1845. Duffy then gathered a group of still younger men around the *Nation* newspaper, and the events which followed drove them to revolutionary policies. The population had increased very rapidly to 8¼ millions by 1845, and the standard of living was so low that a large proportion subsisted almost entirely on potatoes. In 1845 the potato blight, of which both the cause and the remedy were still unknown, reached Ireland, and produced a famine which became devastating when the potato crop was again ruined in 1846 and 1847. Fully half a million people died directly from starvation or from typhus and cholera. Millions more were barely kept alive by soup kitchens and the most meager relief, provided largely by private sources, much of it coming from America. A vast exodus by emigration began, and the roads were crowded with refugees heading for the ports to escape to Britain or the United States.

Young Ireland Rebellion.—O'Connell was slowly dying with softening of the brain, and he died at Genoa in May 1847. The Young Irelanders had already seceded from his Repeal Party, and they were appealing for organized resistance to prevent the export of food from Ireland, which only paid the landlords' rents. The bloodless revolution in Paris in January 1848, which

replaced Louis Philippe by a French republic, had encouraged Young Ireland with hopes of similar success in Ireland after the harvest. John Mitchel, a young Ulster Protestant, became the chief advocate of armed rebellion, and the government passed a Treason Felony Act under which he was convicted and deported. The military garrison was greatly increased, and the plans for a rising were forestalled by orders to arrest all the leaders. William Smith O'Brien and all those who were not yet arrested vainly attempted a rising in County Tipperary in June 1848. He, Thomas Francis Meagher, and others were sentenced to death for high treason, and next year they were deported to join Mitchel as convicts in Tasmania.

Fenians.—Many of the Young Irelanders escaped to America or to France, and in the following years devoted themselves to organizing Irish resistance overseas. The Fenian Brotherhood was formed as a secret society in the United States in 1858. It soon extended widely in Great Britain and Ireland, while its central direction remained in America. A fierce hatred of Britain resulted from the vast emigration which began with the great famine; and as the Irish population in America steadily increased, it became a powerful factor in foreign relations. In 1851 the Irish population had declined to 6½ millions, and it had lost 800,000 more by 1861. In Britain and in Ireland the Fenians provoked widespread alarm by acts of violence and political agitation; but another attempted rising in 1867 was easily put down.

Pressure from overseas and the fear of continued Fenian activities compelled the British Parliament to consider practical reforms. William Ewart Gladstone became leader of the Liberal Party in 1867, and as prime minister soon announced that he would disestablish (sunder the state connection of) the Protestant Church in Ireland, which still exacted tithes from an overwhelmingly Catholic people. He carried disestablishment in 1869, and in 1870 also secured passage of an Irish Land Act which conceded the tenant's right to security of tenure, so long as he could pay his rent, and to compensation for improvements. But emigration, chiefly to America, continued to drain away the most active young men and women for many years. The population fell steadily until 1921, when it was around 4,350,000. It became increasingly evident that only a national legislature could organize recovery.

Home Rule Movement.—In 1870 the Home Rule League was founded by an eminent Protestant lawyer, Isaac Butt, who had previously been a leading opponent of O'Connell's agitation for repeal of the Act of Union. Its demand for a subordinate parliament in Ireland was inspired neither by the sanguine nationalism of Young Ireland nor the bitter Fenian hatred of England; but it met with no success until a young Irish landlord, Charles Stewart Parnell, joined Butt's party and began to obstruct all parliamentary business. His unflinching and ruthless defiance in the British Parliament soon attracted other young members, and in 1878 he was elected leader of the Irish Nationalist Party. Butt and his earlier colleagues were soon displaced by such ardent young nationalists as T. M. Healy, William O'Brien, John Redmond, and John Dillon.

While Parnell produced chaos in the House of Commons by systematic obstructions, a new

movement for land reform in Ireland had been started by Michael Davitt. The son of an evicted tenant, he had been imprisoned as a Fenian convict in England. In 1879, after his release, he founded the Land League in the poorest districts of Ireland, to demand fair rents and fixity of tenure. On lines similar to the new trade unionism, he organized the small tenant farmers to resist evictions and refuse payment of exorbitant rents. A means of agitation which could not be prevented as illegal was found in "boycotting" all landlords who became involved in disputes with the Land League, which many of them opposed by threatening to evict those who joined it.

Parnell joined forces with Davitt's Land League and quickly galvanized the whole country by combining the agitations for Home Rule and for land reforms. He sought to obtain a "balance of power" at Westminster by forming a compact party of some 80 members; pledged to support any English party which conceded their demands. Gladstone soon yielded to this pressure by carrying his Land Act of 1881, which set up fair rent courts. Parnell was imprisoned for obstructing operation of the act, but was soon released, while both English parties (Liberals and Conservatives) made overtures about introducing a Home Rule bill. Gladstone split the Liberal Party by proclaiming Home Rule as his policy, and his first Home Rule bill, in 1886, was defeated in the Commons.

Support in Britain for Irish Home Rule had grown widely when Parnell's political career was suddenly wrecked in 1890 by his becoming involved in the divorce suit brought by his parliamentary colleague Capt. William Henry O'Shea. Gladstone then announced that he could not continue his alliance with Parnell, and the Irish Catholic bishops also demanded his resignation, but Parnell would make no concession. A bitter split developed, and only a small minority of Parnellites retained their seats. Parnell fought his opponents with fierce energy but died from exhaustion in 1891. Deprived of his leadership, the nationalist agitation made no progress. Gladstone made a second attempt with his Home Rule bill of 1893, but it was rejected by the House of Lords. Not until 1900 was the Irish Nationalist Party reunited, when John Dillon, who had led the anti-Parnellite majority, agreed to serve under Redmond.

Land Reform.—Years of Conservative government had killed all hopes of gaining Home Rule, when Arthur James Balfour, on becoming leader of the House of Commons in 1895, adopted a new Tory policy of introducing constructive reforms. Local government by elected councils was conceded; administrative departments were created to develop the western counties and to promote agriculture and technical instruction. And in 1903 the Irish Land Purchase Act induced the landlords to sell their estates on favorable terms to the state, which enabled the tenants to buy their farms by terminable annuities. But the drain of emigration continued, and economic progress was stagnant. The agitation for Home Rule lost the driving force that it had derived from being linked with the agitation for land reforms, which were now attained. Redmond's reunited Nationalist Party at Westminster could offer no more than a resumption of Parnell's tactics of independent opposition at Westminster.

A new generation turned from politics to

revive the nationalist idealism of Young Ireland. Douglas Hyde and Eoin MacNeill founded the Gaelic League to preserve and revive the Irish language. There was a similar movement to promote Irish industries. Sir Horace Plunkett began to organize agricultural cooperative societies. Hopes of a Home Rule measure revived when the Liberals won a large majority in the House of Commons in 1903. But disgust with the failure of Liberal promises produced the rise of the Sinn Féin movement, led by Arthur Griffith, which demanded total withdrawal of the Irish members from Westminster, and an intensive reconstruction at home. The prospect changed when Redmond gained the balance of power in British politics, after David Lloyd George's radical budget of 1909 was thrown out by the House of Lords. Redmond promised full Irish support if the Liberals would introduce Home Rule. After the Lords' veto had been abolished in 1911 by the Parliament Act, the third Home Rule bill was introduced in 1912.

Ulster Opposition.—The Conservatives then adopted new methods under Andrew Bonar Law's leadership. They organized violent resistance to Home Rule in Ulster, where they had for years had a compact Unionist majority in the eastern counties around Belfast. In a reckless political campaign, all the leading Tory politicians encouraged the Ulster Unionist leader, Sir Edward Carson, in organizing a provisional government in Belfast. They exploited openly the anti-Irish sympathies of most officers in the British army, which produced a mutiny in March 1914, when the cavalry officers at the Curragh (a military training camp in southern Ireland) resigned their commissions rather than move into Ulster. The younger nationalists formed a national force of Irish Volunteers to assert their rights. Both forces obtained arms in defiance of government prohibitions, and civil war seemed imminent.

The sudden declaration of war against Germany in August 1914, compelled Prime Minister Herbert Asquith to postpone implementation of the Home Rule Act, passed in September, in order to placate the Conservative opposition and restore national unity. Redmond had a sincere reverence for the British Empire as a federation of self-governing Dominions, and he gave his immediate support to Asquith. He asked the government to leave the defense of Ireland jointly to the Irish and the Ulster Volunteers, and undertook to raise divisions of Irish recruits for active service. But the anti-Irish influences at the War Office under Lord Kitchener prevailed. A strong reaction in Ireland set in against Redmond's recruiting appeals, while nationalist meetings and propaganda were suppressed by the government.

Easter Rebellion, 1916.—Meanwhile the Fenian organization had decided to provoke an armed rising in Ireland while Britain was involved in a European war. Its small and secret membership grew as political repression increased. On Easter Monday, 1916, a sudden rising by less than 2,000 men in Dublin, under the leadership of Patrick Pearse and James Connolly, seized the General Post Office and other buildings and proclaimed an Irish republic. They held out for six days while British forces devastated much of the city. Most of the leaders were sentenced to death, and several thousand political suspects were imprisoned or deported to Eng-

Ireland: The Republic and Northern Ireland.

land. The executions were protracted over many weeks, and sympathy for the republic swept the country.

Thereafter, anti-English sentiment grew rapidly, and Sinn Féin candidates won many parliamentary elections. Prime Minister Lloyd George attempted both in 1916 and 1917 to produce an agreed settlement, but the Ulster Unionists demanded exclusion when the Home Rule Act of 1914 should be put into operation. In December 1918, the general election gave an overwhelming victory to Sinn Féin candidates, who demanded an independent republic for all Ireland. Many of them were still in prison but Eamon de Valera had escaped to the United States, and aroused powerful support. The Sinn Féin members of the House of Commons constituted themselves an Irish legislature as Dail Eireann in Dublin in January 1919, and proclaimed the formal constitution of a republic. Lloyd George poured troops into Ireland; and when most of the Irish police resigned, he enrolled recruits from England and reinforced them by a special Auxiliary Force (Black-and-Tans) consisting of demobilized army officers. The Irish Republican Army retaliated by guerrilla warfare. A campaign of systematic reprisals by the British forces included the murder of mayors and local leaders, and the burning of many villages and towns, which culminated in setting fire to a large part of the city of Cork.

Irish Free State.—Lloyd George's brutal methods in Ireland had brought disgrace upon British prestige. Another Home Rule Act, passed in 1920, created two Irish parliaments with very limited powers, one for the six eastern counties of Ulster (of which two had nationalist majorities) and the other for the remaining 26 counties. The Northern Ireland Parliament was formally opened in Belfast in June 1921. But the Irish members had refused to constitute the other Parliament. After secret negotiations Lloyd George formally invited de Valera to London in July to discuss the future. Insisting on absolute equality of status with Britain, de Valera appointed Arthur Griffith and Michael Collins, with other plenipotentiaries, to meet the British Cabinet. As a result the Anglo-Irish Treaty was concluded in London in December 1921, after Lloyd George had delivered an ultimatum threatening "immediate and terrible war" in Ireland if it was not signed at once. Under this threat the Irish delegates accepted certain conditions, including the oath of allegiance to the British Crown, which de Valera had ordered them to resist. But on the main issue there was general consent. An Irish Free State, with Dominion status equal to that of Canada, was established for all Ireland except the six excluded Ulster counties, with provision for their future inclusion by consent.

When the terms of the treaty reached Dublin, de Valera repudiated them. A provisional government was formed by Griffith and Collins, all British forces were rapidly evacuated from Ireland, and the whole administration was handed over. A long and bitter debate in Dail Eireann resulted in ratification of the treaty by 64 votes to 57. But de Valera refused to accept it. A civil war soon developed, and for some months de Valera's forces occupied a large area of the southwest. Griffith died suddenly from overstrain in August 1922, and a week later Collins was shot in an ambush in west Cork. The gov-

ernment was then led by W. T. Cosgrave. Holding office until 1932, it created the framework of the new state and laid the foundations of national recovery.

IRELAND, Republic of. The present state of the Republic of Ireland was established in 1922. In the article IRELAND (q.v.) the geographic and other physical features and the historical background of the island are treated. In the present article the independent self-governing area of Ireland is described under subsections Area and Population, Constitution, Politics, Defense Organization, Education, Culture, Religion, Agriculture, Industry, External Trade, and Communications.

Area and Population.—The provinces of Leinster, Munster, Connacht and three counties of Ulster (the other six Ulster counties are in Northern Ireland, q.v.) with a population in 1946 of 2,955,107 and an area of 26,602 square miles are governed by an independent republican Parliament. Leinster, which covers 7,581 square miles on the east and southeast, contains twelve counties, Carlow, Dublin, Kildare, Kilkenny, Laoighis (formerly Queen's County), Longford, Louth, Meath, Offaly (formerly King's County), Westmeath, Wexford, and Wicklow, and had a total population in 1946 of 1,281,117. Practically half of this number, 550,725, live in

the capital city, Dublin, and its suburbs. The density of population in the rural areas is mainly between 60 and 120 per square mile. The principal towns, after the metropolis, are Dundalk (population 18,562), Drogheda (population 15,715), Wexford (population 12,296), and Kilkenny (population 10,291). Munster, in the southwest, is 9,317 square miles in area and is divided into counties Clare, Cork, Kerry, Limerick, Tipperary, and Waterford. Its population, 917,306, is spread at much the same density as in Leinster in the rural areas of Limerick, north Cork, and Waterford. In the other counties the density is higher, particularly in Kerry, in some parts of which it is between 200 and 300 persons per square mile. The largest city is Cork (population 89,877), on the south coast, which has a good harbor. The cities of Waterford (population 28,269) and Limerick (population 42,970) are the other main population centers in the province. Galway, Leitrim, Mayo, Roscommon, and Sligo, the five counties of Connacht, cover 6,611 square miles of mainly rugged land in the West. The population totaled 492,797 in 1946. Despite the poverty of the soil the density of the rural population is great, a few districts along the seaboard having between 300 and 400 persons per square mile. In south Mayo the population density per square mile is between 200 and 300, while in the rest of the province it ranges between 100 and 200. The principal urban centers are Galway (population 20,370) and Sligo (population 12,920). The three counties of Ulster under the jurisdiction of the Republic of Ireland are Donegal, the most northerly county in the island, Cavan, and Monaghan. Their area is 3,093 square miles and population was 263,887 in 1946. The population density of these counties, except west Donegal, is between 100 and 200 per square mile. In the coastal districts on the west it is higher, being over 400 per square mile in some parts. There are no large urban centers, as the centers of trade for these areas lie mainly in Northern Ireland. While the south, west, and most of the east limits of the republic are the sea coast, on the northeast there is a land frontier 240 miles long through Ulster. Donegal, which lies alongside this boundary, has but a tenuous land connection five miles long with the rest of the republic. In general, the natural increase in population of the country is offset by emigration, which is mainly to Great Britain. Under native government the emigration rate has declined considerably.

Constitution.—The republic is governed under the constitution passed by plebiscite in 1937. The national Parliament consists of the president and two houses—Dail Eireann (House of Representatives) and Seanad Eireann (Senate). The president is elected by the direct vote of the people, and holds office for seven years. On the advice of the head of the government he summons and dissolves Dail Eireann, and he appoints the prime minister (Taoiseach) on the nomination of Dail Eireann. The supreme command of the defense forces is vested in the president, who is aided and advised in carrying out his functions by a Council of State. The representative house of Parliament consists of 147 members elected by adult suffrage under a system of proportional representation. The Senate has 60 members, 11 of whom are nominated by the Taoiseach, 6 are elected by the universities, and

the remaining 43 are elected on a vocational basis which allots representatives to cultural, industrial, labor, agricultural, and administrative interests. The Senate has no power to veto legislative proposals, and is allowed a maximum of 90 days to consider and amend bills sent to it by the Dail.

The executive power of the state is exercised by the government, which is responsible to Dail Eireann and may consist of not less than seven and not more than 15 members. The prime minister nominates the members of the government, who are appointed by the president after being approved by the Dail. Each member of the government has charge of a department of state and is the minister responsible to the Parliament for that department. The departments are finance, agriculture, external affairs, justice, local government, education, lands, industry and commerce, posts and telegraphs, defense, and health and social welfare.

The constitution setting out the organization of government states the fundamental civil rights of the citizens and makes provision for the protection of the personal liberty, freedom of conscience, and free expression of opinion of the citizens. No amendment of the constitution can be made except with the approval of the people given at a referendum, and any legislation passed by the Parliament which infringes the constitution is invalid. The courts of justice may be called on to act as an independent arbiter to decide whether a statute is repugnant to the constitution or otherwise. The courts of justice consist of a Supreme Court, a High Court, a Court of Criminal Appeal, a Central Criminal Court, a Circuit Court, and a District Court. The judges are independent in the exercise of their functions, but administrative functions in connection with the organization of the courts are carried out by the minister for justice, who has the responsibility for the enforcement of law. He controls the police force, which does not carry firearms.

Politics.—Fianna Fail, led by Eamon de Valera (who was in 1938 president of the Assembly of the League of Nations), was in 1951 the largest political party in Dail Eireann, having almost one half of the seats. Against this party, which held office from 1932 to 1948, was an alignment of smaller parties. Of these, Fine Gael is the largest; its principal figures are Richard Mulcahy and John A. Costello (who was Taoiseach from 1948 to 1951). William Norton is the leader of the Labour Party, which is rather small as organized workers tend to vote for other parties. Its main strength is in rural rather than urban areas. Clann na Talmhan, a party which is almost completely confined to Connacht, is led by Joseph Blowick; it is interested mainly in the problems of small holders in the west. A small party led by Sean MacBride (minister for external affairs in 1948–1951) entered the political arena in 1948 and helped to defeat de Valera. This party, Clann na Poblachta, suffered an eclipse in the 1951 general election. Independent deputies maintain the balance of power between Fianna Fail and the other parties, and the election of a government depends frequently on their support. Differences in policy between the parties are slight. There is unanimous opposition to the continuance of partition, the severance of the six Ulster counties from the jurisdiction of the Irish Parliament. Partition conditions foreign policy, on which

there is also unanimity. While being anti-Communist, all parties have decided on a policy of neutrality in the event of war. As long as partition is maintained by Britain the Irish government will not enter into a military alliance with the anti-Communist countries. The government felt that to join the Atlantic Pact, one clause of which guaranteed existing frontiers, would mean the recognition of the border as permanent. All parties are pledged to a scheme of social welfare, the extension of health services, and the provisions of adequate housing. The actual differences between the parties arise more from personalities and past history. There are Irish ambassadors in the United States of America, Spain, the Vatican, Great Britain, France, Canada, and Australia, and Irish representatives also in Switzerland, Portugal, Norway and Sweden, Netherlands, Lebanon and Syria, Italy, Germany, Belgium, and Argentina. These countries have diplomatic representatives in Ireland. In international affairs, Ireland actively participates in the Organization for European Economic Cooperation and advocates closer European collaboration. Representatives of the republic attend the Council of Europe at Strasbourg, and the minister for external affairs is a member of that body's Committee of Ministers.

Defense Organization.—The Irish army had a strength of only 6,000 in December 1950. The Fianna Fail Party maintained that a permanent establishment of 12,500 is essential to form a well trained nucleus in the event of war. According to Fine Gael, 8,000 would be sufficient and as much as could be armed. As the republic is outside the Atlantic Pact, it finds great difficulty in obtaining military equipment. Besides the army, there is a small air corps and an Irish Naval Service whose main function is to patrol territorial waters and protect the fishing. The volunteer reserve, which undergoes annual training in camp, was 36,000 strong in 1950, about one fifth of its wartime strength. Recruitment to the defense forces is voluntary.

Education.—The constitution acknowledges the right and duty of parents to provide for the education of their children, and the state provides free primary or elementary education, which is compulsory up to the age of 14. The Department of Education pays grants to colleges for the training of teachers of all religious denominations, and it pays the teachers of primary schools. Secondary schools are under private control but are subject to examination by the department, which lays down the curriculum and gives grants on a capitation basis to the upkeep of the schools and pays the greater part of the teachers' salaries. Vocational schools, controlled by the local authorities and maintained partly out of local rates (taxes) and partly from grants from the central fund, are established in all the cities, the principal towns, and some rural areas. They provide technical training for apprentices to trades. University education is given at the three constituent colleges of the National University of Ireland—at Dublin, Cork, and Galway—and at the University of Dublin (Trinity College). The number of university students is over 7,000 each year.

Culture.—The teaching of the Irish language has a special place in Irish education. It is an essential part of the courses in primary and secondary schools, and it has a special place in university education. In many schools, all the

subjects, except English, are taught through the medium of Irish. This is because it is a policy laid down by all political parties to foster the native language, which declined considerably in the last 100 years of English rule and is now the everyday language of only some districts in the south and west. In the Institute for Advanced Studies, the government established schools of research in cosmic physics, higher mathematics, and Celtic studies; and the National Museum, National Library, and National Gallery, supported by the government, collect objects, books, manuscripts, and paintings of cultural and artistic value. Subventions are paid to cultural bodies—such as the Abbey Theatre and learned societies—and a scheme to coordinate artistic and cultural work under a director of fine arts was undertaken in 1951. (See also separate articles on CELTIC LANGUAGES; CELTIC PEOPLES; GAELIC LITERATURE; IRISH ARCHAEOLOGY; IRISH ART AND ARCHITECTURE; IRISH LITERARY REVIVAL; IRISH LITERATURE IN THE ENGLISH LANGUAGE; IRISH MUSIC.)

Religion.—The vast majority of the inhabitants of the republic are Roman Catholics—in fact, 94.3 per cent in 1946. The minority consisted of 4.2 per cent Protestant Episcopalians and less than 1 per cent Presbyterians. The Roman Catholic population is increasing since 1926, but the other religions are declining. The census for 1946 showed, however, an increase in the number of infants of the Protestant religions, but the birth rate among Roman Catholics is consistently higher than that among the other religions. Protestants are much fewer in the provinces of Munster and Connacht than in Leinster, but they are most numerous in the three Ulster counties. They are stronger in urban than in rural areas. All the churches are organized on an all-Ireland basis; both the Roman Catholic and Episcopalian primatial sees are at Armagh, in Northern Ireland. The constitution guarantees freedom of religion, and religious differences are not the lines of political division. Each political party has members of all religious persuasions, and various members of the government have been Protestants, as was the first president under the 1937 Constitution, Dr. Douglas Hyde. The most important of the minor religious groups in 1946 were the 8,355 Methodists and the 3,907 Jews. Practically all the Jews were in Dublin city, where they have a flourishing community. The Society of Friends is a small body numerically but plays an important part in commercial life. See also IRISH CHURCH HISTORY.

Agriculture.—Farming is the largest single industry in the country, and practically one half of the workers are employed directly on the land. Three quarters of those engaged in agriculture are farmers and their families, while the paid agricultural employees are but one quarter of those in the industry. The size of farms may reasonably be divided into three groups—subsistence holdings under 30 acres, medium farms between 30 and 100 acres, and large farms over 100 acres. The smallest group predominate in Connacht and the three Ulster counties, while the medium farms are more usual in the other provinces. The largest holdings, which are most common on the rich grasslands of the limestone central plain, play an important part as fattening lands in the country's cattle export trade. More typical, however, of Irish agriculture is mixed farming, in which tillage provides mainly for

the feeding of livestock with perhaps some barley, wheat, and sugar beet for sale. The farmers' main business is the breeding and rearing of livestock, principally cattle. Pigs are reared mainly on the small farms, on which poultry rearing is also a usual side line; there are few specialized poultry farms. Sheep are reared on the uplands and brought to the lowlands for fattening. Dairying predominates in Munster, where the cooperative movement, owing its origin at the end of the 19th century to Sir Horace Plunkett, inspired the establishment of creameries. Fishing is but of local importance and gives little employment. Before World War II the total agricultural output was absorbed almost equally into three channels—consumption on the farms, the home market, and the export trade. Between 1939 and 1945 the export trade consumed only one fifth of the output, but in the postwar years this increased to practically the prewar position. During the war the country had to produce to meet the needs of the home population. Much more wheat was grown and, like other countries, the farmlands were not adequately fertilized. To provide food for the home market, a system of compulsory tillage was introduced. As a result, at the end of the war in 1945 the soil was depleted and agricultural output had fallen. In 1949 a ten-year scheme of land rehabilitation was initiated by the Irish government for the improvement of farms. Drainage is the main part of the project, which plans to reclaim 4.5 million acres of nonproductive or underproductive land. The Department of Agriculture gives credit facilities to enable farmers to purchase fertilizers. This work received aid mainly by loans from the United States under the European Recovery Program.

Industry.—Ireland's poverty in mineral deposits and its political domination by England in the 19th century are among the reasons why it had little industrial development. In the republic, however, since the foundation of the state efforts have been made to produce power in the country instead of depending on imported coal. The Shannon hydroelectric station, constructed between 1925 and 1929, initiated modern power development; 40 per cent of the Shannon supply is used for industrial purposes, and the demand for electricity led to further hydroelectric development on the rivers Liffey, Erne, and Lee. Electricity is made available throughout the country, and is applied to agriculture under a rural scheme organized by the Electricity Supply Board, a state company which controls electrical development. Modern mechanical methods are used by another state company, the Turf Board, which is helping to replace imported fuel by producing peat from Irish bogs. The virtual collapse in the supply of imported fuel during World War II caused greater dependence on peat than ever before, and in the years after the war a plant was erected to use peat for the generation of electricity. The first peat-fired generating station was established at Portarlinton, in County Laoighis, on the bog which extends across the central plain of Ireland. Industry expanded after 1922 and continues to develop. In 1950, one fifth of the working population was engaged in industry, as against one tenth in 1926. Government planning achieved a scattering of industry, and many small towns were revitalized by the location of new factories in them. There is a social as well as an economic aspect in the policy

of industrial development, in that it brings employment to rural towns and helps to keep the population rural while reducing dependence on foreign suppliers for products which can be produced in the country. A number of industries depend for their raw material on agriculture. Bacon factories and meat-canning plants are scattered throughout the state. Sugar-beet processing is carried on at Carlow, Thurles, Mallow, and Tuam and these practically supply all the home needs in sugar. Beverages are manufactured mainly from barley, and by far the largest brewery is that of Guinness, located in Dublin.

A third of the agricultural machinery used by farmers is made in the country. Leather and clothing manufacture rapidly expanded under native government. Light industries dependent for raw materials on foreign imports—such as the making of aluminum utensils, enamelware, electric bulbs, and electrical equipment—were set up to supply the home market. This rapid expansion of industry was carried out despite the lack in the initial stages of skilled labor, and the result was felt during World War II, when the republic suffered much less from wartime shortages than might have been expected had the industries not been established. The establishment of cement factories has provided material for a drive initiated by the state to provide adequate housing. In 1926, 27.2 per cent of the population was badly housed, but by 1946 this was reduced to 16.8 per cent.

External Trade.—Agricultural products are the mainstay of the export trade of the republic. Live cattle are roughly one third of the total annual exports. Eggs, meat, beer, stout, and Irish whisky are other substantial items of export. The traditional customer for these is Britain, which purchases three quarters of the total exports. This position is kept up by trade agreements, which guarantee to the republic prices on a long-term basis and commits Britain to supplying certain quantities of coal and raw materials in return. These guaranteed prices are usually tied to those paid to the English farmer, and increases to home producers in Britain benefit Irish farmers. In return, the republic is committed to send most of its exportable surplus of foodstuffs to Britain. One eighth of the total exports of the republic go to Northern Ireland, and about one half of that to other European countries. Exports to the United States of America are negligible. The principal Irish imports are machinery and electrical goods, textiles, coal, vehicles and parts, maize (corn), mineral oils, fats, and motor spirit. Consumption goods are less than one third of the imports, while the rest is made up of materials for industry and agriculture and other capital development. More than one half of the republic's imports are from Britain and, despite its small size, the republic ranks about fifth among Britain's customers. Imports from the United States of America are second in importance, and are slightly greater than those from the continent of Europe. There is a substantial deficit between the value of exports and imports, which is met largely by invisible income. The most important item of invisible income derives from tourist traffic, which is encouraged by the government. Tourist receipts are a tribute to the charms of Ireland as a holiday resort and also to the abundance and variety of food available at moderate cost. British visitors in the years after World War II took ad-

vantage of the nearness of Ireland to escape the austerity imposed on them in England, while the international reputation of the beauty spots of Wicklow, Connemara, and Killarney, and the abundant fishing, shooting, and hunting facilities, attracted many. Another source of invisible income is interest on external assets. In 1920 the republic had substantial investments in Britain, and these were increased during World War II, when there was a reduction in imports. After 1945 some of these investments were repatriated to cover capital development in Ireland and to meet the deficiency between income and expenditure—which was due to the purchase of machinery. One of the difficulties of Irish trade is the disparity between dollar expenditure and dollar earnings. In the years between the first and second world wars this did not create any problem, due to the convertibility of sterling into dollars. The development of the dollar-earning potentialities of the tourist trade helped, after 1945, to meet Ireland's dollar deficit.

Communications.—The rail, road, and canal transport services in the greater part of the republic are nationalized, being operated by Coras Iompair Eireann. The roads are maintained by local county councils, aided by grants from the government; they are the basis of the Irish communications system. The nationalization of transport was essential to coordinate the three main services and to avoid the financial collapse of the railways. One of the major problems created by the partition of Ireland is in transport, as the Great Northern Railway has road and rail services on both sides of the border. The area served by this company, which is not nationalized, covers the north of Leinster and the Ulster counties, and is the link between Belfast, in Northern Ireland, and Dublin. The canals, which date from the 18th century, link Dublin to the Shannon and to the Barrow; they carry an appreciable amount of heavy goods, mainly fuel and agricultural produce. The railways carry much heavy freight as well as passengers; their financial position, however, is insecure, and many branch lines are closed as uneconomic. To help to maintain essential supplies during World War II, the government set up Irish Shipping Limited; it created a merchant fleet which was expanded in the postwar years. In air communications the republic has an important position, being on the western fringe of Europe. The customs-free airport at Shannon is an international air station and provides excellent facilities for the Atlantic air routes. A national air service is operated by Aer Lingus Teoranta, which operates direct services from Dublin Airport to Paris, Amsterdam, London, Liverpool, Glasgow, and Manchester. The Department of Posts and Telegraphs operates the telephonic service; there are automatic exchanges in the large cities. It also controls the radio service, which is paid for by the licensing of receivers; broadcasting is carried on from studios in Dublin and Cork on two medium wave lengths.

National Library of Ireland.

HISTORY

The Irish Free State, antecedent to the Republic of Ireland, was established on Jan. 15, 1922, as outcome of the Anglo-Irish Treaty of Dec. 6, 1921, which gave Ireland the status of a

British dominion. The meetings of Irish and English representatives in the negotiations leading to the treaty were largely brought about and inspired by Sir John and Lady Lavery in that great portrait painter's studio in London. Six of Ulster's counties, however, which had accepted Home Rule in 1920, chose to remain part of the United Kingdom as Northern Ireland (q.v.). After long dispute, an agreement made on Dec. 3, 1925, fixed the boundary between the Irish Free State and Northern Ireland.

The year 1922 brought civil war in the Irish Free State, for that country was bitterly divided on the issue of accepting the treaty of 1921. On January 7 the Dail (Parliament) ratified the treaty by 64 votes to 57 and on the 14th, meeting as the Southern Parliament of Ireland, again ratified it. Meanwhile, on January 9 Eamon de Valera left the Dail, while Arthur Griffith as president and Michael Collins as premier prepared to implement the treaty according to their signed word. The text of the Irish Free State Constitution was published on June 15th. Elections for the Dail held the following day resulted in a majority for the new constitution of 58 members to 36. After the elections, there was a battle in Dublin for the Four Courts (the courts of justice) between the government forces and republican rebels, at the end of which the priceless records of Ireland went up in smoke. On July 6, de Valera declared civil war, accusing the provisional government of military dictatorship supported by British "big guns." The civil chaos overwhelmed Griffith's sensitive soul and he died August 12 mourned even by his opponents; William Cosgrave succeeded him as president of the Dail. The country suffered another loss on August 22 when Collins was killed in an ambush. The civil war continued until the end of May 1923. In August, the general election returned only 44 Republicans out of 153, for the people required peace even at the cost of accepting the treaty. De Valera refused from prison to take the oath of allegiance to Britain, a prerequisite to entering the Dail. Among the many schemes introduced by Cosgrave at this period were the sugar-beet industry and the Shannon Electrical Supply—"sweetness and light" in the words of Swift.

The Imperial Conference of 1926 in London led to the Statute of Westminster, which placed the dominions on an equal footing with Britain. In March, de Valera, putting aside Sinn Fein, formed the new Party of Fianna Fail (Warriors of Destiny). He finally took the oath of allegiance (no doubt under the Euripidean sense—"the tongue hath sworn but not the mind") and entered the Dail on July 9, 1927. Yet another leader was lost the following day, when Kevin O'Higgins, Cosgrave's leading minister, was assassinated. He had been in close communication with the British Cabinet on a scheme of Irish dominion unity. With O'Higgins passed any possibility of Ulster becoming a political part of Ireland for a generation. A Public Safety Act then passed widened the scope of treasonable acts.

By 1932 Fianna Fail had penetrated the country, at a general election winning 72 seats to 56 by Cumann na nGaedheal, Cosgrave's party; Independents and Labour held 24 seats. In July de Valera commenced an economic war against Great Britain, Ireland's chief customer, with results dubious to the economy of both countries. On Jan. 4, 1933, a further general election gave de Valera 77 seats to Cosgrave's 48, and others 17.

On May 3 the oath of allegiance to Britain was abolished. In 1934 an important pact was made based on Irish cattle exports and coal imports from Britain, Ireland's main exchange always being meat for the product of the mines.

In 1936 the Constitutional Amendment Act removed the king from all internal authority in Ireland, and the office of governor general (held by James MacNeill in succession to Timothy Healy) was abolished. At the same time, by the External Relations Act the king's name was restored for use in external affairs, but subject to the orders of the Executive Council.

General elections on July 1, 1937, gave de Valera 69 against 48 Fine Gael, Labour 13, and Independents 8. On that date, also, a new constitution was approved by plebiscite; it went into operation on Dec. 29, 1937. In place of Irish Free State, the name Ireland (in Gaelic *Eire*) was restored; the constitution assumed the inclusion of Northern Ireland within the nation's territorial limits. De Valera made an agreement with Neville Chamberlain, British prime minister, on April 25, 1938, for the return of the ports of Cobh, Berehaven (Bearhaven), and Lough Swilly to Irish control. In June, de Valera obtained an overall majority, and Douglas Hyde, founder of the Gaelic League, was installed as president. As a result of the report of the Banking Commission, Irish currency remained tied to sterling. A Treason Act was passed in March 1939 because of the bombing campaign by the Irish Republican Army (then a revolutionary group) in Britain, and in April summary arrest and trial was declared for state offenses; the I.R.A. was outlawed on June 23. When World War II began in September, Ireland declared neutrality; it also objected in 1942 to the use of bases in Northern Ireland by United States forces. Though the government remained neutral, a large number of Irish volunteers from southern Ireland passed into the British services. The Irish names in the honor and casualty lists did much to mitigate the adverse effects of Ireland's neutrality in the British mind. The Shamrock Club, in London, preserved the names of 10,000 "neutrals in uniform."

In 1945 Sean T. O'Kelly was elected president of Ireland. During his presidency de Valera lost and then regained power. Under a coalition, on Dec. 2, 1948, the External Relations Act of 1936 was repealed by the Republic of Ireland Act, and thus the last link with the British Empire was broken. The Republic of Ireland was proclaimed on April 18, 1949.

The Irish Free State had been an active member of the League of Nations (de Valera served as president of the Council in 1932, and of the Assembly in 1938), but the republic was thrice denied membership in the United Nations by the veto of the Soviet Union. Nevertheless, Ireland was a member of six of the specialized agencies of the United Nations and also of the Organization for European Economic Cooperation, and in 1949 it became one of the sponsors of the Council of Europe. However, the republic refused to join the North Atlantic Treaty Organization, declaring that while it was in full sympathy with its aims it could not cooperate therein while the partition issue remained outstanding.

At the general elections of Feb. 4, 1948, de Valera's Fianna Fail Party had been placed in a minority by a coalition of parties under John Costello (Fine Gael, Clann na Poblachta, Clann

na Talmhan, and Labour). The new foreign minister, Sean MacBride, took the extreme but logical view of Irish Republicanism, and expounded it personally in Britain, France, and the United States. However, his party (Clann na Poblachta) was overwhelmingly defeated at the elections of May 30, 1951, and de Valera, without an overall majority, took office. His Fianna Fail Party won 69 seats, against 78 for all other parties. De Valera, surviving all recent history, continued to urge the ending of partition by "friendly approach" to Northern Ireland and the British government. Meantime, the vital questions of Irish life remained at the mercy of successive and bitterly divided factions on the issues of farming, fisheries, and forestry. Under the coalition, James Dillon advanced agriculture, and new efforts were made to replant a treeless island. Rural life was rapidly declining, owing to emigration of the youth to towns at home and abroad; Dublin had collected one sixth of the population of the whole republic. The youth (particularly the female) were leaving Ireland at every opportunity to work in Britain. To popularize rural life, the Muintir na Tire, a social, nonpolitical organization, was working efficiently under Father John M. Hayes. The census of April 8, 1951, showed that the population was still under three millions (provisional figure: 2,958,878).

SHANE LESLIE,

Baronet of Glaslough, County Monaghan.

IRELAND ISLAND, one of the Bermuda Islands. See BERMUDA.

IRENÆUS, *i-rē-nē'ūs*, **Saint**, Christian prelate, a father of the Greek Church: b. about 130; d. unknown. He was reared in Asia Minor, where he was a pupil of Polycarp, and became apostle of the Gauls. In 177 he was bishop of Lyon. According to tradition, he suffered martyrdom in the persecution under Emperor Septimius Severus.

IRENE, *i-rē-nē*, the name of three empresses of the Eastern Roman (Byzantine) Empire.

(1) **IRENE** (752-803), an Athenian by birth, was married in 769 to Leo IV, and following his death in 780 she became regent during the minority of their son, Constantine VI. Zealous for the re-establishment of image worship, she summoned a church council at Nicaea in 787 which decreed the restoration of images to the churches and defined the veneration due to them. When Constantine was proclaimed sole ruler in 790 she was forced to abdicate, but her title of empress was confirmed in 792. For five years she plotted to regain power, and in 797 she caused her son to be seized and put to death. Thereafter she was sole ruler until 802 when, the patricians having repudiated her in favor of Nicephorus, her minis-

ter of finance, she was dethroned. She was exiled to Lesbos, where she died the next year.

(2) **IRENE DUCAS** (1066?–?1120) was the wife of Emperor Alexius I Comnenus. After her husband's death in 1118 she conspired with her daughter, Anna Comnena (1083–?1148), to place the latter's husband, Nicephorus Bryennius, upon the throne instead of her own son, John II Comnenus. When the plot failed she and her daughter retired to a convent.

(3) **IRENE** (d. 1161) became, in 1146, the first wife of Emperor Manuel I Comnenus. The marriage had been arranged by her brother-in-law, Holy Roman Emperor Conrad III.

IRENE, i-rèn', **Sister**, Roman Catholic religious: b. London, England, May 12, 1823; d. New York City, Aug. 14, 1896. Originally named Catherine Fitzgibbon, in childhood she moved to the United States, and in January 1850 she joined the community of the Sisters of Charity, at Mount Saint Vincent, taking the name of Mary Irene. She became sister superior of Saint Peter's School, Barclay Street, New York City, in 1856, and in 1869 she founded, and became director of, the city's first home for deserted children, later known as the New York Foundling Hospital. She continued to head the institution until her death, and also founded the Seton Hospital for Incurables at Spuyten Duyvil.

IRETON, ir'tèn, **Henry**, English parliamentary commander and regicide: b. Attenborough, Nottinghamshire, 1611; d. Limerick, Ireland, Nov. 26, 1651. He was graduated at Trinity College, Oxford, and in 1629 took up the study of law at the Middle Temple. With outbreak of the civil war he joined the Parliamentarians, fighting at Edgehill in 1642 and Gainsborough in 1643, and in 1645 commanding the cavalry on the left wing of Oliver Cromwell's army at the Battle of Naseby; he was wounded and captured, but made his escape. In 1646 he married Cromwell's daughter, Bridget. From 1645 he was a member of Parliament, taking a prominent part in the negotiations which made that body subservient to the army. He helped frame the ordinances for the trial of Charles I, was one of the king's judges, and signed the death warrant. In 1649 he accompanied Cromwell to Ireland as second in command, and the next year was left by him in that island as lord deputy. He captured Carlow, Waterford, and Duncannon in 1650, and Limerick shortly before his death. Buried in Westminster Abbey, after the Restoration in 1660 his body was taken up, suspended from the gallows with that of Cromwell, and buried in the same pit.

IRGIZ, ir-gèz', river, Soviet Central Asia, in the west central part of the Kazakh Soviet Socialist Republic, 270 miles in length. It rises in the southeastern slopes of the Ural Mountains, and flows in a southeasterly direction to enter Lake Chelkar Tengiz (northeast of Lake Aral). The small town of Irgiz, on the river of that name, lies 220 miles southeast of Aktyubinsk; several caravan routes converge here. Another Irgiz River, 300 miles long, is a tributary of the Volga, which it joins opposite Volsk after a westerly course through the Kuibyshev Region.

IRIARTE, Tomás de, Spanish poet: b. Orotava (Tenerife, Canary Islands), Sept. 18,

1750; d. Madrid, Sept. 17, 1791. He was a nephew of Juan de Iriarte (q.v.) and was educated under the direction of his elder brother, Fray Juan Tomas de Iriarte, and later in Madrid with his uncle. At the age of 17 he wrote a drama (in verse), *Hacer que hacemos*, and at this early age he began translating dramas from French for the theaters of the city. So successful was he at this work that some of his original dramas were produced. On the death of his uncle in 1771, he succeeded him as official translator in the office of the secretary of state; and five years later he was appointed archivist to the supreme war council. In 1787 his works were published in six volumes in Madrid. A goodly part of his energies was taken up in quarrels with the critics of the day and with some of his literary contemporaries, the most notable of which was Juan Pablo Forner (1756–1797), who in turn, lashed him without pity, and sometimes without reason. Through the intrigues of his enemies Iriarte was summoned before the Inquisition in 1786, on the charge of propagating French heretical doctrines. But he was able to satisfy the ecclesiastical authorities as to his orthodoxy. Iriarte did much translation and wrote poems and dramas, and attempted other forms of literary work, but his fame today rests on his fables in verse, which are counted by far the best of their kind in Spanish. Their excellence is due not so much to the poetic talent of the author, which was not very great, as to the interesting form in which the fables are thrown, the ingenuity of many of them, their simplicity, vivacity, grace, and appearance of naturalness supported by fertility of invention. These *Fables* became immensely popular, and were translated into most of the languages of Europe. Perhaps the interest in them in Spain was increased by the belief that, under the guise of fable, Iriarte was holding up to ridicule many of his literary detractors.

IRIARTE, or **YRIARTE**, **Y OROPESA**, è-ryär'tà è ò-rò-pá'sà, **Juan de**, Spanish poet: b. Orotava, Tenerife, Canary Islands, Dec. 15, 1702; d. Madrid Aug. 23, 1771. He was the nephew of Tomas de Iriarte (q.v.). Educated in the College of Louis the Great, in Paris, he went to Madrid in 1724, where he became clerk in the Royal Library (1729) and ultimately librarian (1732). Owing to his linguistic ability he was appointed official translator to the secretary of state (1742); and the following year he was elected a member of the Academia Española. He composed hundreds of epigrams and sonnets, and also poems in Latin. Besides a Greek paleography, he published a notable catalog of the Greek manuscripts in the Royal Library.

IRIARTEA, ir-i-är'tè-à, a genus of palms, all South American, marked by smooth, tall stems and pinnate leaves with somewhat triangular leaflets. The best-known species is the pashuiba palm (*I. exorrhisa*), which has aerial roots. The wood is very hard.

IRIDACEAE, i-rì-dä'sè-è, in botany, a natural order of endogenous plants, mostly herbaceous, though a few are somewhat shrubby. They usually have either rootstocks or corms. The leaves generally are sword-shaped, in two rows and equitant. The perianth is six-partite and often very beautiful, in some regular, in

others irregular. There are three stamens, with the anthers bearing outward. The fruit is a three-celled, three-valved capsule. The family (the iris family) yields about 900 species in 60 widely distributed genera throughout the temperate and tropical zones. Some are hardy perennials, others for early summer growing, and there are a few hothouse varieties. Iris, gladiolus, and crocus are familiar examples of the order. Saffron and orrisroot are the principal economic products.

IRIDESCENCE, ĭr-ĭ-dĕs'ĕns, the intermingling and interchange of the spectrum colors on surfaces. Typical surfaces which produce iridescence are those of soap bubbles or mother-of-pearl. The iridescence is produced by the minute irregularities of the surface which, in reflecting white light, split it up into its constituent colors by the phenomenon of interference. The word comes from the Greek *iris*, meaning rainbow.

IRIDESCENT GLASS. See GLASS.

IRIDION (Polish *Irydyon*). The dismemberment of Poland, still more, the disastrous Polish revolution of 1830, had bred the sentiment of national hatred against the oppressors, but Count Zygmunt Krasinski (q.v.), in all his poetry, cautioned his people against hate as an expression of patriotism and preached inner perfection as a means of obtaining the highest good for his country. His work, *Iridion*, which appeared in Paris in 1836, is a poem-drama of exquisite beauty, based on Krasinski's reading of Montesquieu, Gibbon, and Niebuhr. In this poem he wished to give a picture of the fall of pagan Rome and the triumph of Christianity, and tried to show that it was not Greek hatred, but Christian humility, that renovated the Roman world. In the days of the domination and corruption of the Caesars, Iridion, who is represented as of Greek ancestry, sought vengeance against the Rome that had betrayed Athens and throttled Corinth. His mother was a priestess of Odin, and after her death he gave his sister to Heliogabalus, so that she might unsettle the emperor's mind. Iridion, as prefect of the Pretorians, urges Heliogabalus to conspire against Rome. The African Massinissa, versed in magic, persuades him to arm the Christians. Iridion, in the Catacombs, falls in love with a Christian maiden, who thinks that he will bring about the millennium. But just as he appears to be victorious, the bishop of Rome denounces his militancy. He returns to the northern gods of his mother. Heliogabalus and his sister perish. Massinissa tauntingly tells Iridion that Christ will some day rule over Rome, and puts him into a lethargic sleep. He does not awaken until 1835 in the north, but he now loves Christ's cross and has abandoned all ideas of revenge. *Iridion* was translated from the German and French by Martha Walker Cook, in *The Undivine Comedy and other Poems, by the Anonymous Poet of Poland, Count Sigismund Krasinsky* (Philadelphia 1875).

LEO WIENER.

IRIDIUM, ĭ-rĭd'ĭ-ŭm, a metallic element resembling platinum in its general properties, and occurring in nature in the metallic form, alloyed, usually, with platinum and osmium. It is found in the Soviet Union, South America, and Tasmania. Iridium was first definitely identified, in

1804, by Smithson Tennant, who found it in the residue left after dissolving platinum from its ore with aqua regia; in the residue was also found osmium, generally in alloy as irodoamine (q.v.). Separation of iridium from other metals which are included in the platinum group is difficult; for the usual processes employed, the more extended works on metallurgy and the chemistry of the metals must be consulted. Iridium is frequently obtained in the form of a spongy gray mass, or a gray powder; but by heating either of these to whiteness, and subjecting them to compression, the metal may be brought into the form of a compact, lustrous mass resembling steel. In this form it is harder than iron, and somewhat malleable when hot, though brittle when cold. At ordinary temperatures it has a specific gravity of about 22.4, being among the heaviest substances known. Its specific heat is about 0.0323 at ordinary temperatures, and its coefficient of linear expansion (Fahrenheit) is about 0.000039. Its melting point is very high, the estimates given by various authorities ranging from 3,600°F. to 4,500°F. Compact iridium, after being strongly heated, is insoluble in all acids, and is not affected by air or moisture. The metal has the symbol Ir. and an atomic weight of 193.1 if O = 16. It forms numerous salts.

IRIDOSMINE, ĭ-rĭ-dōz'mĭn, a natural alloy of iridium and osmium in varying proportions, is a hard, slightly malleable mineral, crystallizing in hexagonal prisms. It usually contains some platinum, and, frequently, other metals of the platinum group. While found with deposits of platinum in the Ural Mountains, and in small quantities elsewhere, its chief source is in placer deposits in southwestern Tasmania, discovered in 1925. No primary source for these placers has yet been found. This compound metal is silvery white and resists attack of all known acids, and hence is of great value in chemical and electrical industries. The Tasmanian metal is found in grains of such size and quality as to be immediately available for nibs of gold pens.

IRIGA, ĭ-rĕ-gā, town, Philippine Islands, in Camarines Sur Province, Luzon, 22 miles by rail southeast of Naga (formerly Nueva Caceres). Northeast of the town is an extinct volcano, of the same name, 4,023 feet above sea level. The town, the largest in the province, is located in a fertile agricultural region. Pop. (1939) 31,005.

IRIGOYEN, ĭ-rĕ-gō'yān, Hipolito, Argentine lawyer and statesman: b. Buenos Aires, 1850; d. there, July 3, 1933. He was of Basque ancestry. Following the revolution of 1890, in which he took an active part, he became leader of the Radical Party, opposed to the wealthy landowners. In 1916, with adoption of the secret ballot, he was elected president of the republic. He undertook a program of labor reforms, and opposed his country's entry into World War I in 1917. With expiry of his term in 1922 he retired from the presidency, being succeeded by Marcelo Torcuato de Alvear, likewise a member of the Radical Party. He was reelected president in 1928 for a six-year term, but disorders broke out in September 1930 and he was driven from the presidency by the Conservatives, led by José Francisco Uriburu. Released after a brief imprisonment on a warship, he became reconciled with Alvear, who was exiled in 1931. The two

were suspected of instigating the unsuccessful revolt of 1932.

IRIS, i'ris, in Greek mythology, daughter of Thaumás and Electra, sister of the Harpies, the fleet golden-winged messenger and servant of the Olympian gods, especially of Zeus and Hera. Iris was originally the personification of the rainbow, though she does not appear in the Homeric poems as the goddess of the rainbow. She is sometimes represented as a beautiful virgin with wings and a variegated dress, with a rainbow above her, or a cloud on her head exhibiting all the colors of the rainbow. Iris is the name of a planetoid.

IRIS. See **EYE**.

IRIS FAMILY, a family of monocotyledonous herbs, mostly perennials with tubers, corms, or rhizomes, and usually with an acrid flavor. About 800 species belonging to more than 50 genera have been described from temperate and tropical climates, mostly from South Africa and tropical America. They are characterized by two rows of leaves, the outer of which fit over and protect the inner (equitant); regular or irregular perfect flowers which are frequently handsome; perianth six-parted, the other floral organs in threes; and many-seeded, three-celled fruits (capsules). Some species have been used as food in countries where they are native; others furnish rootstocks which are used for making perfumes, especially orris; some few have been employed to a limited extent in medicine but the species most widely popular are cultivated for ornamental purposes. Of these last the most important genera are *Iris* (fleur-de-lis), *Gladiolus*, *Freesia*, *Crocus*, *Tigridia*, *Tritonia*, *Sisyrinchium*, *Ixia* and *Belamcanda*, elsewhere described.

The plants of the genus *Iris* constitute one of the chief ornaments of the northern regions of the globe, and usually grow in wet places, bearing flowers of various colors, but the prevailing tint is blue. The common wild iris or flag (*I. pseudacorus*), common in Europe and also found in the eastern United States, has yellow flowers of large size and long swordlike leaves. The gladdon or stinking iris (*I. foetidissima*) is a British species, with bluish flowers. The favorite garden sorts are mainly florists' varieties of the two species *I. germanica* (the German or bearded iris) and *I. laevigata* (the Japanese iris), and their hybrids with other types. Also used in gardens are *I. xiphoides* (the English iris); *I. persica* (Persian iris); and *I. susiana* (Chalcedonian iris). The roots of *I. florentina* supply the orris root of the drugstores. Several wild species are found in the United States.

IRISH ARCHAEOLOGY. Prehistoric and ancient remains in Ireland are noteworthy for three outstanding features: the importance of the Bronze Age; the great flowering of Early Christian art; and the wealth of field monuments to be seen throughout the country. The Bronze Age in Ireland is notable not only for the large amount of material—bronze, gold, burial pottery, and other objects, but also because of the influence exercised by Ireland on other areas. The Early Christian period saw the development of artistic endeavor which reached its zenith in the 8th century, was interrupted by the Viking invasions, but was ultimately enriched by them in the ac-

quisition of new motifs so that a splendid renaissance resulted in the 11th and 12th centuries. While much of this is the domain of the art historian it is also that of the archaeologist, whose methods enable style sequence to be fitted to a chronological framework, and whose excavations help to provide fixed dating points and also yield a picture of the everyday life. The field monuments of all types and periods—megalithic (great stone) tombs, burial mounds, open or defended habitation sites, monastic remains—are to be found in remarkable profusion, and excavations of these are yielding profitable results. Methodical excavations in Ireland on an adequate scale were rare prior to the 1930's. In 1932 a five-year program was initiated by the Harvard Archaeological Mission to Ireland, and from 1934 onwards Irish archaeologists were able to excavate important sites with the aid of state grants. These activities have resulted in a changed picture of several periods and aspects of Irish archaeology, but an immense amount remains to be done—on whole classes of monuments in some cases, and to fill the gaps in our knowledge of others.

Mesolithic Period.—Attempts to indicate a Palaeolithic occupation of Ireland must be regarded as disproved or dismissed for lack of proof. Kilgreany cave, claimed by the Bristol Spelaeological Society in 1928 to show Palaeolithic habitation, was re-excavated by the Harvard Mission in 1934, and the earliest evidence of human activity there was found to be Neolithic. Implements of limestone found on the Sligo coast and held to be Palaeolithic (Mousterian) led to a prolonged controversy, but those found *in situ* were not implements, and those which are admitted to have been humanly manufactured were not *in situ* and are therefore of doubtful date. Geologically, Palaeolithic occupation of Ireland is not impossible, as clear evidence of mild interglacial periods has been found. One of the difficulties of the recognition of Palaeolithic industries is the limitation of abundant flint supply to the northeastern corner of the country, and industries of other materials are less easy to recognize.

Some of the large flint implements from the northeast have also been claimed to be Palaeolithic, but are now established as belonging to the Mesolithic cultures—which are the earliest definite evidence of a colonization of Ireland. These cultures, associated with the postglacial transgression of the sea which resulted in the 25-foot Raised Beach, have been divided into two phases, Larnian I and Larnian II (named from the site at Larne, County Antrim), and are regarded as being in large measure derived from the Upper Palaeolithic (Creswellian) of Britain. The Larnian is mainly represented around the coast of Antrim and Down, but work since 1946 has shown that it extended much further south—to the coast of Louth and Dublin.

Neolithic.—The vast quantities of flint implements which are the remains of the Larnian culture represent a food-gathering people, and their economy persists in certain manifestations of the Neolithic—though essentially the latter marks the introduction of agriculture and the keeping of domestic animals. On the River Bann, hearths sealed in the diatomite clay are believed to be associated with fishing and the drying of fish, and have yielded Neolithic pottery and pointed flint implements (Bann flakes) which are the

development of flints of the preceding Larnian cultures. Similarly, the settlements on the sandhills presumably represent seasonal activities, and in them have been found Neolithic pottery (and also later material). A more settled economy is attested by the discovery of Neolithic habitation sites at Lough Gur, County Limerick. The first of these sites was discovered in 1939, and a series of excavations was conducted on them during the 1940's. The importance of the Lough Gur evidence is the finding there of Neolithic (and Bronze Age) houses—round and rectangular in plan. The inhabitants depended largely for their sustenance on cattle-raising and to some extent on small scale agriculture. A remarkable site at Lyles Hill, near Belfast, consists of a bank enclosing an area of more than 12 acres, at the center of which is a cairn (mound of stones) covering a cist grave. The bank and the layer under the cairn contained immense quantities of Neolithic pottery sherds. The Neolithic period saw the introduction of the custom of building megalithic tombs. These tombs are of various classes in Ireland and, on the available evidence, the earliest type appears to be the so-called "horned cairn," in many examples of which pottery and other grave furniture (leaf-shaped flint arrowheads) of Neolithic type have been found. These graves consist essentially of long galleries of upright stones originally roofed with slabs and divided into a series of compartments by pairs of jamb stones. The front of the tomb is distinguished by a crescentic façade, sometimes of imposing proportions. The burials are usually by cremation. These tombs are found in the northern half of the country; their distribution extends from Carlingford Lough, on the east coast, to County Sligo, on the west. Related to them are more elaborate structures ("lobster-claw cairns"), found in Sligo, Mayo, and Donegal, on the northwest. They consist of an open circular or oval court surrounded by uprights and a series of segmented galleries which are entered from the court.

Other Neolithic burials of nonmegalithic type include burials (cremated and inhumed) in stone cists, with or without mounds, and in ring-barrows (very low mounds with surrounding ditch and bank).

The pottery gives some indication of cultural connections—with the British Neolithic A (Windmill Hill), which is part of the western group of European ceramics, and with the Neolithic B culture, whose roots are in the Baltic area. The Windmill Hill type of pottery in Ireland is much more widespread than is the Neolithic B, but shows such local developments as heavy and exaggerated rims with ornament. As well as these round-based vessels, a heavy, coarse, flat-based ware occurs which has affinities with the "grooved" ware of Britain (as at Scara Brae, in Scotland) and perhaps ultimately with the Horgen ware of Switzerland and the French (Seine-Oise-Marne) gallery graves. This pottery lasts on into Bronze Age times and provides one of the roots from which the cinerary urn develops.

Bronze Age.—The Bronze Age in Ireland began soon after 2000 B.C., and the preceding Neolithic appears to have provided a short introduction (perhaps of only a few centuries duration) which overlapped with the Bronze Age. In the Neolithic, however, the foundations for the succeeding culture were laid, and the same sites (for example, those at Lough Gur) continued to

be inhabited. Ireland's importance in the Bronze Age was doubtless due as much to the development of the farming economy introduced in Neolithic times (and for which so much of the land was eminently suitable) as to the mineral deposits which the primitive metallurgists exploited. Gold was obtained from the Wicklow area, and possibly elsewhere. Copper mines which were worked in ancient times are known in Waterford, Cork, and Kerry. It is uncertain how much of this ancient working is genuinely prehistoric, but some of the mines (Mount Gabriel, County Cork) show significant similarity with the Bronze Age mines of the Austrian Tyrol.

In the Early Bronze Age Ireland produced certain metal types which are either Irish developments or distinctive variants of those known elsewhere and, because of their distinctiveness, these can be traced outside of the country, thus giving evidence of the role of Ireland in the general development of early metal-working. Among the Irish exports are flat axes (at first of copper, then of bronze, some with characteristic ornament), halberds (blades which are mounted at right angles to the shaft), gold lunulae (crescentic neck ornaments), and gold disks (so-called "sun disks"). The export routes of these commodities, or perhaps the routes followed by craftsmen, can be traced across Britain and to northern and western Europe, on the evidence of objects which are either actual exports or local copies.

The vigorous Irish Early Bronze Age was an amalgam of developments from the Neolithic together with influences from different sources. The beaker folk (known from their special type of pottery vessels), who spread through Europe from the Iberian peninsula, were formerly thought to have had little influence in Ireland. Since the 1930's, however, their pottery has been found in many megalithic tombs of the gallery grave class, in the sandhills, and in the Lough Gur area in considerable quantity—on habitation, burial, and ritual sites. The beakers belong in part to the international type (with S-profile), in part to the special type (A—beakers) developed in Britain.

Gold lunulae found in the Iberian Peninsula are a backwash along a route which brought many influences to Ireland—the origin of the lunula, the idea of the halberd, flint javelin heads polished on both faces. The splendid "passage graves" (megalithic tombs consisting of a chamber reached by a long passage—the whole covered by a great mound) provide the most spectacular result of Iberian influence. Some examples are of enormous size—Newgrange, Dowth, and Knowth, on the Boyne, cover each an acre in area. They tend to group in cemeteries: on the Boyne, County Meath; at Loughcrew, County Meath; at Carrowkeel, in County Sligo; and in a simplified form at Carrowmore in the latter county. Usually placed on hilltops, these tombs are impressive monuments. Some evidence (pottery) is available for their beginnings in the Neolithic, but they belong in the main to the Bronze Age. A feature of the Irish passage graves is the art (magico-religious carvings) on the building stones of such tomb groups (Boyne, Loughcrew, and elsewhere). This art has affinities in Malta, in the southwest of Spain, and even in the Canary Islands; the carvings at Newgrange are paralleled by those in Gavrinis, Brittany. Other rock scribings, not in tombs but on rock surfaces (mainly in the southwest of Ireland),

indicate further connections with Iberia, in this case with Galicia—possibly due to the arrival of early metal-workers from that area.

Gallery graves different in structure from the horned cairns are of two types—the one typical of the northern part of Ireland, the other, very numerous, of the south. Both are dated to the Early Bronze Age by the beaker and other pottery found in them. Independent in origin, but influenced by the ornament of the beakers, is the “food vessel,” so-called because it frequently occurs with burials of unburnt bodies (laid on the side with flexed limbs) and was intended to contain food for the journey to the next life. In its variety of form and ornament the food vessel is an index of the many sources of influence and inspiration which were combined in the Early Bronze Age culture of Ireland. The food vessel is used also with, or to contain, cremated burials; and later, in an enlarged form, it becomes an urn in function and type.

Other structures which may contain burials but which are primarily ritualistic in purpose are the stone circles and related monuments. Though not as impressive as the British “henges” (Stonehenge, Woodhenge, and others) they are varied and numerous in Ireland. Because of their ritual use, lack of finds makes them difficult to date, but one at Grange, near Lough Gur (possibly the finest, consisting of a ring of great uprights placed inside an earthen bank), is securely dated to Early Bronze Age times. A large enclosure with standing stone and grave at the center, surrounded by bank and fosse, at Furness, County Kildare, is similarly dated.

Middle Bronze.—The Middle Bronze Age is a continuation and development of the Early Bronze Age. Known metal forms persist or evolve—the knife-dagger grows into the large dagger and the rapier. A rapier found at Lissan, County Derry, 30 inches in length, is one of the most graceful examples of prehistoric bronze casting. The bronze flat axe is now provided with side flanges and stop ridges, and becomes the “palstave.” Native type spearheads with loops for attachment to the shaft are influenced by the Continental riveted type, and hybrid forms result. Work in bar gold tends to replace the products of sheet gold of earlier times, and twisted gold torques are used as neck ornaments or perhaps, in the case of the great examples found in Tara, as waist ornaments.

Late Bronze.—The Late Bronze Age, which began sometime after 1000 B.C., is characterized by a great increase in the amount and variety of the equipment. The quantity of bronze and gold of Late Bronze Age date in museums is very large, and hoards (associated finds of objects) are a feature of this period. The new metal types—leaf-shaped swords, socketed axes, trumpets, buckets, cauldrons, gold gorgets (neck ornaments), and many others—are not a development of Middle Bronze Age examples, but represent new cultural influences from different sources. How far these are the result of actual invasion, and how far it is justifiable to connect them with the introduction of the Celtic language, are matters of speculation and controversy. The numerous innovations, however, did not cause Ireland to lose her initiative. Some of the gold ornaments are peculiar to the country, others, and some of the bronzes, are distinctive native adaptations of Continental prototypes. The bronze cauldrons exemplify this; magnificent specimens of

craftsmanship, they are translations into metal of pottery vessels—the Greek *dinos*. They are part of the evidence that Ireland received impulses not only from the northern and western continent but also along the old Mediterranean-Atlantic route.

In the Late Bronze Age there was also cultural continuity from the earlier period. If, as seems likely, the grouping of urn burials in flat cemeteries owes its origin to the Continental urn-field cultures, the parallel development of cairns with numerous graves (multiple-cist cairns) must be ascribed to a development from the megalithic tombs. A group of urn burials found in a “ring fort” at Cush, County Limerick, is of importance for the dating of such forts, of which there are thousands in Ireland. Usually circular enclosures (known in Irish as *rath*, *lios*, etc.), with one or more banks and ditches, they provided protection for the habitations built within them. The Cush example had been deserted as a habitation site before the burials were inserted in it. It therefore predated the Late Bronze Age burials, and we have hints on other sites of even earlier beginnings for this class of structure. Accompanying many of these forts, and sometimes built independently of them, are souterrains—underground structures which served as places of refuge and for storage. Crannogs (artificial islands in bogs and marshes), built for the protection of their inhabitants, originated in lakeside settlements in Neolithic times. A small example at RathJordan, County Limerick, belongs to the Early Bronze Age, and a larger specimen at Knockalappa, County Clare, is dated to the Late Bronze Age—Early Iron Age transition.

Early Iron Age.—Several factors make the Early Iron Age the most unsatisfactory period in Irish archaeology. The time of its introduction is difficult to define because of the vigor of the overlapping Late Bronze Age; at Knockalappa, for instance, pottery similar to British Iron Age A accompanied Bronze Age equipment—the leaf-shaped sword, gouge, and sunflower pin. The absence of a Roman invasion means that the Iron Age is regarded as extending to the 5th century, but without precise chronological fixed points. Yet this period is important historically because it is reflected in the great saga literature (the *Cú Chulainn* and the *Finn Cycles*), and it is the time when the notable early historical sites achieved importance. But none of these sites—Tara, Cruachain, Emain, Tlachtga, to name but a few—has been yet excavated. Their investigation should shed much light on an obscure phase.

The 1st century B.C. and the 1st century A.D. see the establishment in Ireland of an Iron Age culture definite in character though limited in distribution and comparatively meager in the amount of material available. The crannog at Lisnacroggher, County Antrim (unfortunately, not scientifically excavated), yielded amongst other objects sword scabbards with curvilinear ornament related to the Iron Age B culture of Britain and ultimately to the *La Tène* of the Continent. The ornament on the scabbards, in common with much of the contemporary Irish Iron Age material, finds its source of inspiration in Britain—particularly North Britain. The development in Ireland is, however, distinctive, and several types are not paralleled outside the country. The outline of the objects and the ornament they bear show a taste for curved forms (in Continental origin, a geometric treatment of vegetal designs)

which later plays so important a part in Irish art development. Brooches, pins, trumpet ends, horse bits of bronze, and inscribed bone flakes (these last found in a passage-grave at Louchcrew), all bear this ornament. Related motives are to be found on stone—at Killycluggin, County Cavan, Castlestrange, County Roscommon, and Turoe, County Galway—on monuments, for which direct Continental prototypes (Brittany) must be sought.

Roman Influence.—Though Ireland lay outside the sphere of Roman conquest, the Roman domination of Britain was bound to have influences on the neighboring island—as did also, in some measure, the extension of Roman power to the shores of Gaul. Roman objects are of sporadic occurrence in Ireland and probably arrived in various ways—by barter, in the possession of refugees from Roman power, and by loot. They belong mainly to two groups. The one, late 1st and early 2nd century A.D., probably reflects unsettled conditions consequent on the imposition of Roman rule in Britain; with these Roman objects native British products were introduced—as in the find of Lambay Island, County Dublin. The second group, of the late 4th and early 5th century, came in as loot brought by Irish raiders who descended on Roman territory when the imperial power was breaking; the objects thus acquired (silver plate, ingots, and coins) were of less importance than were the incidental contacts which resulted in the acquisition of techniques that were added to the repertoire of the native craftsmen. During the Roman period in Britain the Irish artists continued to develop the curvilinear ornament of La Tène ancestry, and applied it now to splendid *repoussé* work in bronze and gold—on gold collars (as from Broughter, County Derry, and Clonmacnoise, County Offaly), on enigmatical bronze disks, and, in a delicate form of cast ornament, on cone-shaped horns from crowns or helmets. But by the end of the Roman period they added millefiori work (the use of multicolored glass rods), niello, and filigree.

The great bank and ditch known as the "Black Pig's Dyke," which runs between County Armagh and County Donegal, is said to have been inspired by the Roman Wall across Britain, though it could hardly have been successfully manned in a military sense and it must have been no more than a precaution against cattle raiding. Great hill-forts, which are a feature of the pre-Roman Iron Age in Britain, are rare in Ireland, but this form of defensive structure occurs in a modified form on some of the royal sites (Tara, Emain, Ailenn) and elsewhere. One, excavated in 1949, at Freestone Hill, County Kilkenny, is dated to the 4th century. Meanwhile, many ring-forts and crannogs must have been in occupation at this time, and also at least a proportion of the numerous promontory forts which are found on the coast. Some examples excavated in County Cork during 1949–1950 did not yield datable finds but showed structural features similar to those in Cornish and Breton promontory forts.

Early Christian Period.—The term "Early Christian" is used for the period from the introduction of Christianity in the 5th century to the late 12th century. The stressing of the *Christian* aspect is justified by the fundamental changes which the Christian faith brought about in the pattern of life and consequently in the archaeological record.

Forts, crannogs, and houses similar to those of pre-Christian times continued to be built and occupied. However, as well as the secular sites, remains from this period include churches (or church sites, where scant remains or tradition mark the places from which wooden or even stone buildings have vanished), monasteries, great and small (and their accompanying memorials—grave slabs, inscribed pillar-stones, crosses), as well as round towers (built largely as refuges from Viking raids) and the dwelling cells of the monks. The monasteries were in some cases modeled on the secular forts—with enclosing bank or wall. What astonishes is their prodigious number—not all datable, and certainly not all of contemporary foundation; but it is clear that already, in the 5th century, ecclesiastical establishments began to be built plentifully throughout the land, and in the 6th the foundation of the great monasteries began—with that of St. Enda of Aran as the first example. Little remains of the buildings of the most famous monasteries, but a site like that on the Great Skellig (off the coast of Kerry)—little more than a bare rock in the ocean—indicates the essentials of the early monasteries. Being in a treeless spot, the buildings were entirely of stone. Small churches and a collection of beehive cells are a reflex of the type of monasticism—eremitical, ascetic to an extreme degree—which produced a multiplicity of buildings instead of the single building of Continental monasticism as established by the Benedictines.

The curvilinear art of the Iron Age survives on pins (hand-pins), brooches (so-called latches), and other minor objects, frequently now with the addition of enamel. But it is Christianized by its use on the monastic sites—on stones with ornament alone, or ornament combined with crosses of various forms. The designs develop in complexity, new motifs such as interlacing and figure representation are added, and the magnificent high crosses of stone result—mainly with geometric ornament in the 8th century, with scripture subjects in the 9th and 10th, and again with ornamental carvings in the 11th and 12th. The illumination of manuscripts of the Gospels gave a new medium for the artists of the monasteries. Examples are the books of Durrow (7th century), Lindisfarne (early 8th), and Kells, the greatest (early 9th). Lindisfarne is but one of the foundations which resulted from Irish missionary activity in Britain and the Continent. The minute complexity of the illuminators' work reacts on the metal workers and enameleurs who originally inspired it, and such treasures as the *Ardagh Chalice* and the *Tara Brooch* are achieved.

Viking Influences.—Relics of the Viking invasions which began in the late 8th century are strangely limited—one large cemetery at Dublin, and sporadic finds through the country. The loot of the raiders carried back to Norway—ornaments, reliquaries, church lamps—is important archaeologically because it is found in dated contexts—mainly in graves of the 9th century—and fills many of the gaps in the Irish record. Irish motifs influenced Scandinavian art and, notwithstanding the shock of the invasion, Irish craftsmen continued to work. The high crosses were still carved, metalwork continued, though the great 8th century overshadows the two that follow and make it difficult to recognize their products. Paradoxically, it is not until after the breaking of the Viking power at Clontarf that the Irish

artist accepted northern motifs and incorporated them in his repertoire, blending them, however, in a manner which was distinctly his own.

Meanwhile church building had developed. The use of mortar (perhaps introduced in the 7th century) made larger structures possible; the roof, formerly of dry-stone corbels, was elaborated, and ornament was used on doors, chancel arches, and windows. But even the beautiful Romanesque churches, with interesting variety of ornament, are small buildings not comparable to those of the Continent. The coming of the Cistercian builders of great abbeys, in the early 12th century, is the herald of the end of the era.

IRISH ART AND ARCHITECTURE.

Ireland's position as an art and architectural country is conditioned by the fact that it is situated at the extreme northwest angle of Europe, far from the center of eastern Mediterranean civilization and thus destined to receive its art impulses at long remove. Insularity retarded invasion in bulk and then insured long periods of incubation so that at well-defined moments the elaborated ideas flowed back into Europe, as for example: the gold trade of the second millennium B.C.; the medieval missionary movement (650 A.D. onwards); or the late 18th century leavening of European literature into Romanticism through Celtic, specifically the Ossianic, epic. The antique Irish ringed cross, revived by 19th-century patriotism, became popular in many places as a memorial of the valorous dead from 1914 onwards.

Iberian explorers of 2,000 B.C. or so opened up the country when they discovered gold in quantity in the streams of the Wicklow Hills just south of Dublin, establishing a tradition of gold-work which was maintained up to the Anglo-Norman Conquest of the 12th century. Late Celtic settlers coming mainly by way of northern Britain from Europe about 250 B.C. onwards brought in the first developed ornamental style, a style destined to reach new heights in the Christian era from 450 A.D.: it continued logically with Norse admixture till the Conquest, a long drawn-out business which destroyed the native development without creating new styles. However, within the core of the English settlement around Dublin in the 18th century a new nationalism developed, enriching the country economically and making Dublin one of the art cities of Europe. After an awkward pause in the middle of the 19th century this renewed itself until fused with Gaelicism and, influenced by native epic, a new art urge appeared; Ireland, which tends to develop along normal European lines, is still individualistic and not entirely uninfluenced by American attitudes.

Dublin remains the art capital and possesses the principal art school (National College of Art), housed indifferently but staffed by a brilliant group of art professors which includes lead-

ing painters like Seán Keating, president of the Hibernian Academy, and Maurice MacGonigal, its curator. The Hibernian Academy, founded in 1820 in succession to the Society of Artists, aims to include in its membership established painters; it holds an annual exhibition available to the public for a month. Adjoining the college is the National Gallery, opened in 1854, regarded as one of the best of the smaller European galleries, a position due to its second director, Henry F. Doyle (1869-1892).

In the same area are the National Library, with a large print collection, and the National Museum, which includes valuable archaeological and decorative art collections offering a wide selection of exhibits to the craftsman desiring foreign models or seeking to emulate the masterpieces of the Celtic and medieval periods in Ireland.

Dublin has also a good gallery of modern painting (Charlemont House), due ultimately to Sir Hugh Lane (drowned in the *Titanic* disaster in 1912) which was intended to house a large collection of modern French masters; owing to a faulty will, these have been retained in London. Belfast, capital of Northern Ireland, has a good combined museum and gallery and an awakening art school; other provincial Irish towns since 1930 have been founding the nuclei of museums and galleries, the permanence and eventual value of which cannot yet be assessed. An Art Act intended to forward organization and development became law in 1951.

Additional annual art functions like the Oir-eachtas Art Exhibition and the Living Art Exhibition give scope to numerous artists having different objectives, while the art centers of the Dublin Painters (7 Stephen's Green) and the Waddington and Dawson galleries, are rarely free of special exhibitions which sometimes include works by noted foreign painters and sculptors, including extremists of various kinds.

Iberian Art.—To the early Iberian settlers and gold seekers in Ireland coming from Spain and Portugal by way of western France and Brittany the first flashes of a definitive art may be attributed, finding its expression in the decorative or symbolic treatment of many of the great stones and flags which form their chamber-and-passage tombs. These are chiefly situated in the Boyne Valley (an Irish "Valley of the Kings") and the adjacent Loughcrew Hills, all in the ancient central kingdom of Meath. It is a residual art long removed from the original representations of goddesses and the like. The same general age, just after 2000 B.C., produced a more systematic style, geometrical in character, applied to gold crescentic neck-ornament, bronze axes, and earthenware. Throughout the Bronze Age proper, decoration of a related character is the sole evidence of artistic expression, borne out by superb series of gold ornaments, gradually becoming more sophisticated as the age advanced; the heavy gold collars of the close of the period reproduce leather armor, bronze neck-guard and shield details, evidence of a new art influence involving northwest Central Europe.

Early Celtic Art.—With the coming of Marnian Celts a more elaborate and still more abstract decorative style was introduced linking Ireland through northern Britain with north-eastern France and Switzerland, where the style achieved a name, La Tène, a noted site on the Lake of Neuchâtel. It became the leading Irish

style for centuries, playing a notable part in the efflorescence of culture between 750 and 1050 A.D. and strongly influencing modern Irish ideas. It is in essentials the Greek palmette reduced to graceful groups of spirals or scrolls ending in or uniting lobes, either flat or in relief; these latter may meet to form "trumpet ends" or lens-forms disposed throughout the ornament. The classical monument of this art, which may date 250 B.C., is the western Irish *Turoe Stone*, a low rounded pillar over which is cast, like a chasuble, two fields of ornament finished at the end with a Wall-of-Troy or simple fret ornament; it is sculptured in low relief carving, the field being pocked to give emphasis to the pattern, and the whole may have been covered with a thin plating of gold for which treatment there is both literary and archaeological evidence in connection with other cult objects. In the main, however, the art is preserved or recorded as the main decoration of metal wares, brooches, scabbards, chariot- and house-fittings, mirrors, and the like. Certain unexplained bronze disks in which stylized human faces are worked out in embossed *La Tène* ornament, and a cylindrical gold torque of great magnificence found on the shore of Lough Foyle, Northern Ireland, are notable masterpieces of the metalworker's art. Actual sculptures in the round exist, but they share the continental Celtic sculptor's lack of appreciation for style and anatomy.

Christian Period.—The succeeding epoch, 250–550 A.D., one of political disturbance, is rather arid of art achievement, but with the coming of Christianity in the 5th century and the growth of flourishing monasteries this condition was gradually replaced by a fine flowering of a native art inspiration, the materials selected helping to mark out the periods of the development; that of the great illuminated manuscripts, that of the tall, free-standing high-crosses and that of the metal shrines, all of course overlapping in one way or another. A faded Celtic ornamental style so-called *Ultimate La Tène*, occurs in bronzes, etc., and, reaching into the earliest mss., fore-shadows the astonishing revival of Celticism of the succeeding age.

Illumination.—Irish illumination as such is incomprehensible apart from the missions sent forth by St. Columba (Columcille) of Derry, who died in 597 A.D., dominating northern England and much of Scotland. In the former area, surviving Celtic ornament might be found alongside animal scrolls introduced by the Angles and other Germanic tribes. Rich Byzantine manuscripts were introduced from Italy by St. Augustine of Canterbury, in 596, and by Benedict Biscop of Wearmouth and Jarrow, in northern England, about 675. The Irish style came therefore to be compact of Celtic, Germanic, and Byzantine motives in an essentially Byzantine framework. The three principal monuments of this distinctive and impressive art are the *Book of Durrow* (County Kildare), the *Book of Lindisfarne* (off the English northwest coast, a monastery founded for St. Aidan and a party of Irish monks by St. Oswald, Anglian king or Northumbrian), and the *Book of Kells* (County Meath); all three books belonged to abbeys under the influence of Iona (off the southwest Scottish coast) and, of course, the Columban Rule. It can be presumed that the three works date to about 700–775,* and many other manuscripts bear

the same imprimatur of Celticism—for example, the *St. Gall Gospels*, in Switzerland. *Lindisfarne*, by reason of its delicacy of treatment, is nearest the supposed model; *Durrow*, in its relative simplicity, appears as a "try-out"; while *Kells*, despite the grave stylization of the portrait element, is, by its wealth of coloring, the extraordinary fineness of its interlacement, its luxuriant fancy, and the numerous small and quite irrelevant colored drawings, the outstanding work of the group and epoch. The *Codex Amiatinus*, in the Laurentian Library at Florence, is reasonably regarded as best illustrating the original foreign exemplar or exemplars. The book-contents, apart from text, are mainly pages given up to portraits of Christ, the Virgin, the Evangelists, the Symbols of the Evangelists, the Christ sign in Greek (XP) which is the tour de force of these manuscripts, and columnar arcades enclosing the Eusebian canons (gospel cross references); some pages are all ornament: such pages may now be regarded as originating in earlier book-cover and colophon-page designs, the East Mediterranean source of which is already known. Despite the seeming disorder of the decoration—spirals, inter-lacements, and frets—a rigorous panel arrangement dominates, and the presence of the Byzantine mosaicist and marbleworker in spirit is unmistakable. A special tribute has to be paid to the fine naturalistic birds which characterize *Lindisfarne*.

Sculptured Crosses.—Peace essential for such prolonged and delicate labors disappeared with the Viking raids, about 850 onwards, on the Irish and British coasts, especially those about the North Channel. Irish genius now expressed itself in superb high-crosses which are in effect the projection of manuscript ideas in stone, even as to form, namely, a combination of the Greek and Latin crosses with the normally surrounding circle of the former set squarely at the junction of the arms of the cross. Their main date is perhaps 800–950 A.D., with an extension to the 12th for some atypical varieties. Byzantine inspiration furnished northern Britain with two tall stone crosses, those of Bewcastle and Ruthwell, which provided the general idea for the intense Irish development; they clearly derive from the *Cross of Constantine* at Jerusalem, adjusted to an Anglo-Saxon carved-timber tradition. Columban influence stands behind the movement. *Kells* (County Meath) has thus a number of exemplars and *Durrow* has one notable cross, but the finest examples are those of *Monasterboice* (County Louth) and *Clonmacnoise* (County Offaly). Armagh can be taken as the center point of the whole northern series. An early group at Ahenny (County Carlow) is notable for its almost wholly ornamental character; and in one the wedge-shaped foot, as if pared for fitting to its pyramidal base, indicates that these lofty monuments derive in part from a long line of carved timber monuments of which no exemplar survives. The leading groups, scripture-crosses as they were called, show numerous panels illustrating parallel scenes from the Old and New Testaments but with free use of purely decorative items derived from the manuscripts. Often the cap is of house-form and illustrates not only contemporary architecture but shrines of the house type. The importance of these crosses in the history of European sculpture is the essential theme of the works on the subject by Arthur Kingsley Porter (1883–1933).

* These dates are controversial. See IRISH ARCHAEOLOGY—Early Christian Period.

Art Metalwork.—Celtic craftsmanship which left a permanent tradition of fine metalwork behind it was strengthened by the importation of workers with a new style by St. Patrick and other missionaries. The typically Irish penannular brooch, a long pin with a large ring and a derivative of the Roman buckle, occupies an important place in this phase of Irish art history; in due course the ring and head were flattened and the terminals formerly turned back, then flattened, and finally unified, providing three main surfaces which came to be decorated in the richest manner possible but in a style closely related to that of the illuminated manuscripts and the high-crosses. The high peak of this series is the *Tara Brooch*, found on the east coast of Louth; an attached silver chain of fine wire mesh shows that it was one of a pair. This gem of western European art is made the recipient of numerous techniques; gilding, niello, chasing, enameling, and jewel-cutting, the last mentioned, small human heads of garnet(?) at the hinge joining the chain to the ring. This ring is a near parallel in design to the ring of the principal Irish high-cross (Monasterboice), evidence of interinfluence. The second primary jewel of the same epoch is the *Ardagh Chalice* (County Limerick) a minstral two-handled chalice with deep bowl, a very short stem, and a domical base with flattened foot; the handles, highly ornate in character and having close relation with brooch details, are embellished with red and deep blue enamel bosses. A typical manuscript band of ornament, gold panels separated by enamel bosses, surrounds the cup; underneath this are the names of the Apostles (including Paul), emblematic of the Last Supper, Christ being represented by ornamental medallions of gold spirals in a Greek cross setting on either side of the cup. The interior of the base, which could be observed when lifted up by the priest, is a crystal surrounded by several zones of gold paneling set off with amber (now largely missing). The piece is rightly regarded as the outstanding jewel of its kind for the age. The writer dates these two ornaments on the basis of accumulated techniques to about 950–1000, but a date two centuries earlier is often mentioned; and a similar diversity of view may arise regarding the latest jewel added to this short series—a reliquary belt composed of hinged and curved sections with paneled ornaments, the *Moylough Belt* (County Galway), a late discovery: some of the ornaments simulate high-cross heads of a type usually assigned to the 11th century, for example, that of Drumcliffe, County Sligo.

Eleventh- and 12th-century metalwork is illustrated by a number of elaborate book-shrines, bell-shrines, house-shrines, and crozier-shrines, mostly of a high standard of workmanship but signalized by the intrusion of Viking ornament and a progressive coarsening of detail. *St. Patrick's Bell* (5th century) and its silver shrine (about 1100 A.D.) constitute outstanding Irish insignia. The latter is a tabernacle form, the front decorated with panels of coarse gold spirals in a book-cover setout; the back is a perforated silver panel with swastika motive, based on Continental transennae, or shrine-panels in carved stone, a constant feature of Irish metal shrines; the narrow sides are filled with a coarse wire scrolling, and have rings for suspension. This epoch ends with two notable monuments: the ark-shaped processional *Shrine of St. Man-*

chan (Boher, County Offaly), having an elaborate array of stylized figures, the saint, and his community; and the processional *Cross of Cong* (County Galway), a shrine made for a portion of the True Cross. The general design of the latter is that of the *Constantine Cross*, with scalloped sides, the front being filled with gilt panels of animal-style interlacement and a crystal at the center. The very tall high-cross of Tuam, which is decorated in a low-relief interlacement in the same style, brings the main Irish development to a logical close. Shortly after these objects were made the Anglo-Norman conquest of Ireland began (1169) and a long period of artistic chaos ensued.

Pre-Conquest Architecture.—The architecture of the pre-Conquest period is divided between two very different modes based respectively on wicker construction and stone corbelled work, assimilated as to style to timber forms now no longer existing. Western Ireland, because of its treeless character and the effective recourse to dry-stone walling, is remarkable for a series of ancient fortifications. The chief examples of these are the remote hill forts of Staigue (County Kerry) and Aileach (County Derry), and the elaborate promontory forts of the Aran Islands, notably that of Dun Aonghusa, all belonging to the Celtic epoch. Even in the beginning of the metal age, well-built tombs with entrance passage and corbel-built chamber characterize the Boyne Valley and other cemeteries. Details of wicker construction are preserved in the Celtic romances, and advert to both circular and rectangular structures. It is the corner-post and gable elements of the latter which contribute leading features to the first stone churches (these often of very limited size). The circular form continued in earliest Christian times as clochain, or beehive cells, for hermits dwelling along the west coast—for example, the laura on Skellig Michael, County Kerry.

From these, an oblong oratory type evolved, still corbelled (such as that at Gallerus, County Kerry). Soon small oratories with erect walls appear (Mac Dara's, County Galway), but the corbelled tradition continued in roof construction right up to the climax of Irish pre-Conquest building, as in Crimmac's Chapel. This is a unique Romanesque gem of the 12th century, replete with twin square towers (implying Rhenish influences), recessed entrance, and tympanum, and a free use of arcades with painted designs within for surface decoration. The features of this insular development are: battered (sloping) walls, the batter lessening as time advanced, sloping door and window jambs parallel to the wall batter, corner antae (piers) on the east and west walls, and projecting square moldings on the gables, the latter details being pictures in stone of features in contemporary timber construction; the gable was topped with a winged finial, itself a timber derivative. Doors were mainly square-headed, with a relieving slab above, usually bearing the Christ sign (Greek cross) or, as at Maghera (County Derry), a sculptured Crucifixion in the style of the high-crosses. From 1000 A.D. onwards, normal arched doors, often deeply recessed with zigzag and human-head ornament, and even interlaced designs thinly sculptured, become common: Killeslin, County Carlow, is a fine example. Chancel arches were similarly treated. The evolution of plan was equally deliberate, the small oratory becoming

the sanctuary in a two-piece plan of which the nave was perhaps three times its area (as at Rahan, County Offaly). No transepts figure in this development, and square apses, where they occur, as in the next epoch, are the rule.

The principal centers for examples of these types are the monastic settlements of Clonmacnoise (County Offaly) and Glendalough, (County Wicklow). Columba's House at Kells (County Meath) illustrates the growth of the clochan or beehive cells through much straining to be the upper chamber or priest's room over a tiny oratory. With the assaults of the Vikings, from the 9th century onward, monasteries were more carefully defended. Thence evolved the tall round-tower, so characteristic of the Irish countryside, consisting of a cylindrical tower with conical stone roof; the door was pitched high above the ground, and string courses carried five or six floors, lighted by slit windows, often four in number, at the top. Their Irish name, *cloig-theach*, indicates that they were regarded as belfries, but they also served as refuges and treasuries. Their period is between 900 and 1050. The finest example, with external string courses, is that of Ardmore (County Waterford). That at Glendalough gives centrality to an extensive monastic settlement. As in other structures, the towers are slightly battered (inclined), that at Ardmore especially so.

Later Developments.—With the introduction of the Cistercian Order by St. Malachy, straight from Clairvaux, France, an end was brought to the traditional modes of the Irish monastery, and with it the native tradition in building. His establishment at Mellifont, in the Boyne Valley, was built in a Late Romanesque manner in 1142, it was followed by others still building when the Anglo-Norman Conquest began. The following centuries are therefore full of building activities. Cathedrals, abbeys, and the like are effectively provincial versions of English and French work, tending in the 15th century to evolve into a subordinate national style; the main feature was a square-tower crowning the transept crossing and the old square apse. Christ Church Cathedral, Dublin, bears ample evidence of its relation to churches of Somersetshire, England, itself not a strong building center. The suppression of the abbeys in the 16th century left them without successors for a long time to come. Notable remains survive at Holy Cross, County Tipperary, and Cong, County Galway. Military architecture began in 1170 A.D. with the erection over a wide area of eastern Ireland of timber castles surmounting high mottes (eminences) and surrounded by baileys (outer walls) and palisades at ground level; it ended with stoutly built stone castles, shadows in plan and general character of Anglo-Norman building in England. The "frontier" citadel of Trim, County Meath, is a good example of military architecture. Abbeys were often castellated, and the frequent presence of battlement motives in quite late church building no doubt re-echoes this earlier age of strife.

With the year 1700 and the absence of any serious threat of an Irish recovery, nationalism came to roost in the English Pale itself and a movement of city embellishment appeared especially in Dublin. By the end of the century numerous public buildings of neoclassic design had sprung up at artistically strategic points in the city complex, mostly associated with the architect James Gandon: Parliament House, the Four Courts Buildings, the Custom House, King's

Inns, and later, in the early 19th century, the General Post Office. The interspaces were filled with good Georgian mansions, many of which boasted superb ceilings and fireplaces. Houses like those of the earl of Charlemont and the duke of Leinster, in neo-Palladian style adjoining fine squares, helped to complete the Dublin architectural scene around 1750. The style, which had many rural triumphs also (like the seat of the Connollys at Castletown and that of the Leinster family at Carton, both in County Kildare, residences of palatial design, extent, and even contents), had sufficient validity to bear translation to colonial America. This further variety of the style is epitomized in the White House, itself built during 1792-1800 by the Irish architect, James Hoban of Kilkenny; the structure has many points in common with Leinster House and the President's House (formerly Vice-regal Lodge), Dublin. Hoban had done much fine work in Carolina before being discovered by Washington, indicating that this fine flowering of American civilization, its Colonial Palladian, can, like much else, have a strong Irish backing. Sculptors now emerged, such as Edward Smith, John Henry Foley, and John Hogan, mostly trained in the Roman school of the time; they began to fill a long vacant gap in Irish art history. A mere handful of wood carvings, some in polychrome and a few recumbent figures of Anglo-Norman grandees, are all that unite the present age with that of the high-crosses in the line of distinguished sculpture.

In the new economic recovery, largely stimulated by the example of the American colonists, the decorative arts began to flourish. Glassmakers from Stourbridge, in England, established in Waterford, at the end of the 18th century, a factory which produced in generous quantity many finely cut forms of domestic glassware, chandeliers, decanters, footed salvers, and the notable salad-bowl forms beloved of collectors. A tapestry school begun near Dublin in the time of Charles II promised remarkable achievements but failed to hold its ground. In Galway, silver almost maintained the traditional link with the past, but in general Irish silver attuned itself to English and French design. An assay office in Dublin ensured high standards not only in metal but technique, and Irish silver is not unreasonably cherished by the collector. The noted *de Burgo-O'Malley Gothic Chalice*, probably made in Galway, indicates that despite unsettled conditions fine aesthetic achievements were possible even in the 15th century.

Minor Arts.—The minor decorative arts like furniture and textiles benefited enormously by the changed conditions: much of the former survives, but owing to the lack of house accounts and illustrated sales lists the art is largely anonymous. On the other hand, the close interest taken by the Dublin Society in linen and cotton print design has left us ample records of the textile industry, though surviving examples, topical or classical figurings for the most part, are very rare. The period of flowering was between 1730 and 1830. Neocolonialism even turned to the native harp and its rich musical tradition; while a personified Hibernia, already on silver-work from 1731 and now a rival to Britannia herself, often became the badge not only of Irish workmanship but of high quality also.

Irish lace (and crochet), because of its international *réclame* and mature excellence, is often

regarded as an old traditional art. In effect, however, it is a 19th-century inspiration which struck surprisingly deep roots, and in a relatively short time it came to equal, if not excel, the products of Brussels and Valenciennes; Limerick and Carrickmacross are the two centers especially associated with the art. While still of interest to the connoisseur, the lacemaking movement has practically disappeared, the victim of a change in fashions.

Ceramics lagged far behind Continental standards. Nevertheless the 18th-century Delamain factory at Dublin held much promise, and the 19th century Beleek factory (County Fermanagh), through its imaginative designs and its unusual mother-of-pearl luster, attracts some tastes and is of interest to American collectors.

Modern Epoch.—The short-lived efflorescence of the latter half of the 18th and early 19th century ended with the Great Famine of 1847. A new trend upwards, terminating in the present republic, then appeared; it was bound up, however, with a reversion to the antique Gaelic background, with its superb epic literature and art. So, from 1890 onwards, there was achieved a new mastery of the Irish consciousness affecting industry, drama, music, and literature. Already a few meritorious painters, like James Barry of Cork (q.v.), a rival of Joshua Reynolds, had demonstrated Irish possibilities. The new wealth of late 18th-century Ireland had given work for many competent portrait painters, later to come, like English painters of the time, under the virile influence of the American painter, Benjamin West (q.v.), president of the Royal Academy, in London. In London at that period was also another American, Gilbert Charles Stuart (q.v.), who, before returning to the United States, dwelt in Dublin and there produced many pictures, including some of the patriotic notabilities of the Irish Parliament; this service was parallel to that which he afterwards rendered the founders of the new republic of the West. The extent to which the Irish painter Nathaniel Hone (1718-1784) may have contributed to the style of these brilliant American painters in the direction of a natural and vital portrayal emancipated from classical and English social conventionalism cannot be overemphasized. Some of the latter's best work is in miniatures, a category in which Charles Robertson (1760-1821) and the more prosaic John Comerford (1770-1782) of Kilkenny also deserve honorable record. The groups just mentioned emphasize the strong forces linking national and artistic growth; however, little divided the artists of this short-lived renaissance in tone from the contemporary English movement, and this is true, of course, of the first painters of free America.

The French movements of the 19th century left Ireland untouched to any serious extent, though the habit of looking to Italy remained constant. The brothers Mulvany, both academic painters, appeared to be on the verge of discovery with their studies of peasant life. Again, the depiction of movement, especially animal movement (which still remains a weak point in Irish painting), received an adequate and, for 19th-century Europe, new inspiration from Michael Angelo Hayes (1820-1877), an interpreter of British military events and Irish genre subjects. Some of his pictures engraved by Rudolph Ackermann (1820-1877), of Düsseldorf and London, acquired wide popularity. James Arthur O'Con-

nor (1792-1841), with his romantic and often moonlit German and Irish landscapes, was, however, no substitute for a Théodore Rousseau or a John Constable—though of sufficient merit to obtain a kind of revival in Ireland about 1940. Daniel Maclise (1806-1870) was certainly a competent painter and of large ideas, though modern taste shows the same disregard for his drama-influenced creations as for those of Lawrence Alma-Tadema: his *Marriage of Strongbow and Eva* (Norman conqueror and daughter of a Leinster king) was long the *pièce de résistance* of the National Gallery of Ireland. We can be thankful, however, for his sympathetic portraits of Thomas Moore, the Irish poet of the early 19th century, and of the English novelists Charles Dickens and Harrison Ainsworth. Ireland became the home of the young English painter, George Chinnery (1774-1825), whose Irish portraits make such a striking contrast to his gracious and much-sought-after portrayals of Chinese and Indian life; he may be quoted as indicating the continuing art life of the Irish capital and its power of attracting genius.

Eventually the appearance at the turn of the century of Walter F. Osborne and Nathaniel Hone, noted landscape painters taught by European experience, indicated lines appropriate to a school not then likely to possess an extensive clientele at home. The great portrait painter, William Orpen, an Irish "Gilbert Stuart," was able to bestride both Ireland and Britain with his lightsome and easy portraiture of interesting personalities. Patrick Tuohy, many of whose paintings are in New York, where he tragically died, might easily have excelled him despite his grimmer handling of reality. Sir John Lavery, a competent society painter whose canvases have enriched the municipal galleries in Dublin and Belfast, and who painted mostly in London, never achieved an Irish vernacular despite valued depictions of Sir Roger Casement and other notable men of the revolution. Irish taste seems to demand a slight cartooning approach, and this is strongly visible in the early work of Jack Yeats, brother of William Butler Yeats, the distinguished poet, in his studies of western peasant life; his later work is indicative of a personality of extraordinary fantasy and dynamic color skill. His popularity and perhaps his status are adumbrated by the fact that a first-day of an exhibition of his works, 21 in all, saw 16 of them sold at a total of £6,000 (Oct. 8, 1951).

The developed Irish school now took shape in the persons of Seán Keating, Seán O'Sullivan, Leo Whelan, and Maurice MacGonigal, influenced by, but by no means following too closely, current European modes: Spain rather than France or Italy attracted them, a throwback to early Iberian sympathies perhaps. The west Irish scene occupied the patternist painter, Paul Henry, while more routine landscape painters like Frank McKelvey and J. Humbert Craig chose the north Irish scene, the former in his later humor clearly deriving some inspiration from the great Corot. The fairy and mythic element found interpretation in the light works of AE (George Russell), the poet, who left no successors: the dream atmosphere of Lady Glenavy's, Patrick Hennessy's, and Cecil Salkeld's studies, the last influenced by Hilaire Degas, is entirely personal to these artists. In Northern Ireland, the distinguished humanist painter, William Connor, has reduced large numbers of agricultural and indus-

trial types to the sympathetic expression of his able canvases. In sculpture there is less to be said: Oliver Sheppard, a robust modeler, has left many pieces which shadow forth ancient epic. Albert Power, most typical Irish sculptor, was a good portraitist and a sympathetic interpreter of children: his fish sculptures in Irish green marbles are special to him. It is usual to swell the tale by including the Irish-Americans, Jerome Connor and Andrew O'Connor, who at an advanced stage in their career resumed their artistic citizenship: both are well known in the United States and are well represented in Irish collections. Augustus Saint-Gaudens (1848-1907), born in Dublin of Franco-Irish parentage and founder of the modern American school of sculpture, can hardly be added to this group. He is, however, represented in the city of his birth by the strongly designed statue in bronze of the Irish tribune, Charles Stewart Parnell (1846-1891), with its striking triangular obelisk.

It is a sign of vitality that a junior school is making its way sunwards: men more sympathetic to the European trend like Fergus Ryan, an urban painter, and Louis Le Brocqy, who has become the *fauve* of a group of which the Northern Irish painter, Daniel O'Neill, may become the leading light. Junior sculptors are Lawrence Campbell, Peter Grant, Miss Hilary Hearne, and Gabriel Hayes, of whom Miss Hearne is the sole modernist, a student of pure form. Rosamond Praeger is a sensitive creator of child studies.

A parallel growth of "Celtic" art marks this new phase and has given us superb *Book of Kells* work, that of Art O Mornachain, and the precious pieces of the metalworker's art by Miss Mia Cranwill—some of them now in San Francisco Cathedral. Medieval Irish art also invaded the goldsmiths' atelier, producing "Celtic" ideas of ornament and even reproductions and adaptations. Enameling, never logically developed in Ireland, found a new expression in the work of Oswald Reeves, mostly subsidiary to metal pieces, but the art failed to maintain itself, in spite of some fine achievements. Greater emphasis may be laid on stained glass of this epoch, whether it be the Romanesque masterpieces of An Tur Gloine (The Glass Tower), the Gothic-Celtic creations of the Clarke Studios, or the frank Renaissance work of Messrs. Earley's workshops, often reminiscent of the glass in Prague Cathedral. Several art guilds—like the Cuala Industries, a Yeatsian foundation, and the notable Dun Emer Guild, noted for superb carpets and embroideries employing pure Celtic design—gave shape and direction to a movement whose outlines have tended in later times to become blurred.

A promising movement to revive Irish Romanesque traditions in architecture naturally accompanied the uprisal, but save for the Honan Hostel chapel, at Cork, and the parish church at Spiddal (County Galway) the movement, especially associated with the name of William A. Scott, has not been intense. The fine Byzantine interior of University College Church, Dublin, has a more magnificent successor in the basilican cathedral of Mullingar, County Westmeath. Romanesque taste, however, survived though in later times contenting itself with Italian hill-country and Spanish-American models and suggestions. The fine 19th-century revival of Gothic produced Killarney Cathedral by A. W. Pugin, founder of the style; the superb twin-towered primatial cathedral in Armagh (architect, J. McCarthy), the

old ecclesiastical capital where St. Patrick established his primitive church buildings in the 5th century, and St. Peter's Church (architect, George C. Ashlin) of the Vincentians, in Dublin.

National Museum of Ireland.

IRISH CHURCH HISTORY. The opening date in Irish ecclesiastical history is 431, when Palladius was sent by Pope Celestine I "as their first bishop to the Irish who believed in Christ." By that time the conversion of Gaul was complete and the conversion of Britain far advanced, so that the extension of the Christian faith to Ireland was to be expected. Palladius was not the person through whom this work was destined to be accomplished. It is likely that he died before this task was well begun, for the traditional date of the coming of his successor to Ireland is 432. This Patricius (Patrick) was a Briton of respectable ancestry who had been taken prisoner by Irish raiders at the age of 16 and sold as a slave to a master in County Antrim. After six years he had managed to escape. Soon he felt within himself the stirrings of a missionary vocation. He studied in Gaul as well as in his native Britain, was possibly for a time a monk at Lerins, in the Mediterranean near Cannes, was certainly a cleric attached to some church like Auxerre before the "desire of his soul" could be realized, and he set foot in Ireland at the head of a band of British and Gallic missionaries.

St. Patrick found Ireland almost wholly a pagan country; he left it at his death predominantly a Christian land. This is the evidence of the *Confession*, a short spiritual autobiography penned by him in the evening of his days. It is the evidence also of Irish records, which begin

to take reliable shape precisely at this period. St. Patrick is thus the Apostle of Ireland, and has been honored as such with a devotion for which there are few parallels from the middle of the 5th century down to the present time.

It is obvious that the Apostle would seek to reproduce in Ireland the church organization which he knew so well in Britain and Gaul. In the way of this, however, there were obstacles which it was difficult to overcome. Chief among these was the lack of cities; of places, in other words, where episcopal sees would normally be fixed. Some deviation from the Continental model thus became inevitable. Another peculiarity, which began to appear in St. Patrick's lifetime and gathered momentum, in extraordinary fashion, about the year 520, was the popularity of the monastic ideal. Before the 6th century ended Ireland was dotted with monasteries and smaller religious houses. Most of these were ruled by abbots, who were priests, not bishops. The result was an increase in the prestige of the abbatial position to a point far beyond what St. Patrick had ever foreseen. Abbots came to represent the highest power in the ecclesiastical order, though never equated in dignity with bishops, who in "honour-price" continued to rank with kings.

Saints and Scholars.—The Golden Age of the Irish Church—relatively short, as all periods of unwonted prosperity are wont to be—may be placed within the years 620–740. High idealism and strict observance within the monasteries resulted in profound peace. The monks held themselves aloof, with astonishing success, from the ambitions, jealousies, and quarrels of the secular states. To outside observers Ireland looked an *Insula Sanctorum*—Island of Saints. Thanks again to the ancient Celtic heritage of education, it was taken for granted that the monks should be no less learned than the poets, brehons, and chroniclers of native tradition. Hence every monastery had its school. Classical literature was introduced and cultivated. The works of the fathers and writers of the church were studied. Irish *literati* became skilled in the writing of Latin prose and verse. Thus the *Insula Sanctorum* became at the same time an *Insula Doctorum*—Island of Scholars.

Missionary Efforts.—Before the 7th century ended the monks had begun to carry Irish sanctity and Irish scholarship abroad. St. Columba (Columcille) of Derry settled in Iona in 563, and from that conveniently situated missionary center sent heralds of the Christian faith to the greater part of what is now Scotland. The Irish mold given to the Scottish Church was retained to the 12th century. In 635 missionaries were sent from Iona to Northumbria, where their work was remarkably successful. Irish missionaries labored, too, in East Anglia, Mercia, and even in Wessex, so that their share in the conversion of England to Christianity is very considerable. Owing to disputes about the paschal date, the close connection between Iona and Northumbria was broken in 664, but Irish influence continued, especially in the monasteries, where the alliance between asceticism and learning was maintained. Beyond the English Channel, in Continental Europe, St. Columban of Luxeuil was a zealous reformer as well as an enthusiastic monk. To the impulse given by his three original foundations in Burgundy, about 50 monasteries in the Frankish kingdom traced their origin. He was famous

also as a preacher of penance. His last foundation was at Bobbio, in northern Italy, a monastery that was to rank as a leading center of culture in Europe in the early Middle Ages. Irish saints and missionaries were to be found also in the eastern Frankish empire. St. Kilian (Cillian) was martyred at Würzburg; and St. Vergil of Salzburg (died 784), active as an abbot, bishop, and evangelist, was yet more renowned as a scholar. We know that he taught the sphericity of the earth and the existence of antipodes. In the 9th century, when the great tide of religious fervor was on the ebb, Ireland was still sending forth teachers to the Continent. Two of these, Sedulius the Irishman (Scottus) and John the Irishman (Johannes Scottus or Scotus, or Eriugena) have left names of distinction, the former as a poet and grammarian, the latter as a Neo-Platonist philosopher and theologian.

Church Decline and Revival.—About the middle of the 8th century monastic Ireland entered on a period of decline. The movement was accentuated by the confusion due to chronic raids (795–837), followed by more sustained attacks and partial settlement on the coast (Dublin, Waterford; and Limerick, in the Shannon estuary) on the part of the Northmen. These singled out monasteries and churches for destruction, in the first place because they were pagans, hostile to Christianity, in the second place because they were freebooters, who found the monasteries rich in artistic and other treasure. As the monasteries were also unprotected, they were easy and rewarding to despoil. The simple fact is that the chief occupations of the Norse during two centuries were robbery, arson, and murder. It is obvious that the losses, religious, cultural, moral, caused directly by them were immense; what cannot definitely be assessed is the indirect damage, due to the impossibility of normal progress, in the three spheres just mentioned, which their presence in the country occasioned. Unfavorable conditions in Rome and in the church generally at this time must also be taken into account. In Ireland, as elsewhere, the encroachment of the secular princes steadily increased. Armagh itself, the primal see, fell into the hands of a local sept, and was ruled by members of it who did not trouble to receive ecclesiastical orders from 957 to 1105. The enslavement of the church was complete.

Hardly had Hildebrand, the energetic Pope St. Gregory VII, died, when the reaction which he sponsored spread to Ireland. By the end of the 11th century it had gathered strength. Another 50 years, and reform on the widest scale was an accomplished fact. Important dates are 1101, when Cashel, the old capital of Munster, was bestowed as a gift upon the church and soon afterwards constituted a metropolitan see; 1106, when the Abbot of Armagh was consecrated bishop and the usurpation by laymen ended; 1111, when a synod held at Rathbresail, under the presidency of a papal legate, divided the country into territorial dioceses ruled by bishops; and 1152, when a synod at Kells, presided over by a cardinal sent for the purpose from Rome, completed the work of reorganization, so that it has never since required substantial alteration. Meanwhile, in 1148, the most distinguished of the reforming prelates, St. Malachy of Armagh, had died at Clairvaux. The old Irish monasteries, with their lands, had become the hereditary possession of lay lords to an extent that made their return to

their original status impracticable. They were therefore abandoned and a new monastic system, that of the Cistercians, similar to theirs in spirit, was introduced in their stead.

Assimilation of the Normans.—The Anglo-Normans invaded Ireland in 1169, and after 80 years of constant fighting they were masters of about two thirds of the country. Early in the 14th century the tide had turned and the Irish princes were winning back more and more of their ancestral lands. In the course of time the Norman lords became largely assimilated, so that it could be said of them that they were *Hibernicis ipsis Hiberniores*—more Irish than the Irish themselves. As there was no difference in faith between the Irish and the Normans, the problems which the church had to face were purely political. In general, the clergy of the two races may be said to have gone their separate ways. The great medieval religious orders flourished—Cistercians, Premonstratensians, Canons Regular, Knights Hospitaller of St. John of Jerusalem, Trinitarians, Franciscans, Dominicans, Carmelites, Hermits of St. Augustine, and Canonesses of St. Augustine. Where the writ of the English king ran he tried to control appointments to bishoprics. Attempts to exclude the members of one race from entering a community predominantly of the other race were condemned as unchristian by the popes. It is remarkable that throughout the whole medieval period no university was founded in Ireland: those who wished to secure an intellectual information of superior quality had to go abroad to find it.

Reformation Era.—When Henry VII mounted the throne of England in 1485 the power of the crown in Ireland was almost nominal. In the course of the half century that followed it became very real. Thus when Henry VIII declared himself supreme head of the church in his realms in 1534, the repercussions in Ireland were immediate. An archbishop who would carry out every royal wish was appointed to the see of Dublin by the king. All religious houses were suppressed. There was not, for the time being, any serious opposition: the local lords were ready to share in the monastic plunder; the prelates were induced to strain their consciences rather than die in what they took to be a passing quarrel; the mass of the people were bewildered and but dimly aware of the issue. The scene was transformed, however, under Edward VI, when the First Book of Common Prayer was introduced. No ability or violence on the part of the king's deputy and servants could get this Protestant liturgy accepted. Hence Queen Mary Tudor found no Protestants in Ireland to persecute. Her successor, Queen Elizabeth, again renounced the jurisdiction of the pope in matters spiritual, re-introduced the Book of Common Prayer, abolished the Mass, enjoined attendance at Protestant worship on Sundays and holy days under penalty of fine. For a decade or so after her accession the law last mentioned was but sporadically enforced.

With the excommunication of Elizabeth by Pope Pius V in 1570 quasi toleration ceased. The religious situation in Ireland was now abundantly clear: on the one side was the bulk of the Irish nation—Gaelic, Norman, settlers of English race and tongue in the medieval towns—immovable in loyalty to the inherited Catholic faith; on the other side was the governmental group, in number a small minority but possessed of the whole machinery of state and determined to use it to

make Protestantism the sole religion of the country. In the revolts of the next 30 years, that of Lord Baltinglas in Wicklow, that of the Desmond's in Munster, that of O'Neill and O'Donnell which spread to all Ireland, religion was never the sole but it was always a primary issue.

A peaceful solution was not found. The might of arms, confirmed by the victory at Kinsale (1601), enabled the English deputy and officials to take over the churches, cathedrals, ecclesiastical property of all kinds, and bestow them on their own nominees, who thus became in Ireland the counterpart and the projection of the Protestant Established Church in England. A university, exclusively Protestant in its constitution, was founded in Dublin by Queen Elizabeth in 1591. Into this church, however, and its university, the people refused to come. Appointments to the various sees were made by the popes, as formerly; and Catholic clergy, whatever the obstacles, continued to minister to their flocks. When persecution became active they went underground; when persecution relaxed they built modest chapels in laneways and remote places. To solve the problem of education, colleges for Irish students were opened abroad, at Salamanca, Louvain, Antwerp, Bordeaux, Compostella, Lisbon, and Rome.

Confederation of Kilkenny.—With the accession of Charles I came a small measure of relief. The king, refused supplies by his Parliament, was prepared to sell some concessions or "Graces" to the Irish Catholics for money. But persecution was soon renewed and was continued under Strafford. Growing discontent led to open revolt among the Catholics of Ireland in 1641. By the summer of 1642 the insurgents, who had set up legislative and executive machinery (the Confederation of Kilkenny) held the whole country with the exception of a few of the larger towns. Soon afterwards Charles I and his Parliament were at war. The Confederation was quite ready to lend aid to the king on the two conditions of complete religious toleration and a free and independent Irish Parliament. Pope Innocent X sent a nuncio, Rinuccini, archbishop of Fermo, to be his representative with the Confederation. Negotiations with the king and with his deputy in Ireland brought disunity into the Confederate councils, and the insurrection was already a failure when Charles I was beheaded and Rinuccini left Ireland for Italy. A month later (March 1649), Oliver Cromwell arrived in Dublin with a powerful Parliamentary army to begin a campaign that was to result in the annihilation of Irish resistance.

Protestant Ascendancy.—For the defeated Catholics there was no mercy. The "Cromwellian settlement" deprived them of all their lands in three out of the four provinces. Any men of mark whose lives were spared were ordered to transport themselves to Connacht, the poor province between the Shannon and the Atlantic seaboard. Soldiers and adventurers from England were settled on the confiscated lands. All Catholics were expelled from the towns and their places taken by Protestant burghers. In the sequel, the planters remained a relatively small minority but they possessed nearly all the good land, and with it the wealth of the nation, while the Catholics, despite predominance in numbers, were treated as an inferior class, tolerated only because they could serve the new owners.

Even after the Restoration of Charles II

(1660), the position of the Catholics in Ireland improved but little. Very few of those who had suffered for Charles I recovered their property. The Catholic population generally was miserably poor; priests were fined, imprisoned, and persecuted. Towards the end of the reign the "Popish Plot," invented by Titus Oates, brought about the imprisonment of many Catholic bishops and the hanging at Tyburn, London, on the evidence of perjured informers, of the primate and archbishop of Armagh, Oliver Plunkett (1681).

James II sought to place Catholics and Protestants on an equal footing, as well in Ireland as in Britain. When James lost the throne of Britain he found support in Ireland, where he landed in March 1689. A parliament, summoned by him to meet in Dublin, enacted that there should be complete religious toleration. The campaign which followed ended in his defeat and in the Treaty of Limerick (October 1691), one article of which guaranteed to the Catholics of Ireland such privileges "as they did enjoy in the reign of King Charles II." But this article was destined to remain a dead letter.

Penal Laws.—The 18th century, for the Catholics of Ireland, was the period of the Penal Laws. Catholics were excluded from the professions and from the more lucrative forms of trade; they could not become magistrates nor grand jurors, nor members of a town corporation. All ecclesiastical dignitaries were ordered to leave the country. Catholics were not allowed to have schools; and if educated abroad and ordained priests, were not permitted to return. After the death of George I (1727) these laws were less rigidly enforced. During the reign of George II it became clear that the Catholic Church could not be eliminated, and a mild movement for the repeal of the Penal Laws could be initiated (The Catholic Committee, 1757). Relaxations began in 1771, and Catholic relief bills were passed in 1778, 1782, 1792, and 1793.

Emancipation.—Before the Act of Union (of the kingdoms of Great Britain and Ireland) was passed in 1800, William Pitt, the English prime minister, let it be understood that the Catholics would be freed from their disabilities before the law, virtually at once. But King George III was so violently opposed to the suggestion that nothing could be done. The question was revived in 1805. Soon afterwards the Catholics of Ireland received a new and eminently capable leader in the person of Daniel O'Connell. Against the proposal that in reward for the granting of emancipation the British government should have a veto on the appointment of Irish Catholic bishops he set his face resolutely. When Catholic Emancipation was finally granted by the Duke of Wellington's government in 1829, its value was not diminished by any such condition. After 1829 Catholics in Ireland were free in legal theory; but their social status was still low, their proportion of the national wealth negligible, their educational facilities meager, their general condition backward and condemned to remain so for decades to come.

Protestantism Divided.—While the clergy and laity of native Irish race, the Anglo-Normans, and the old English merchants of the towns refused to accept the supremacy in matters spiritual of the English sovereigns, and the doctrines of the Reformers, the contrary was true of the officials and other new settlers of English race, and of some of the highly Anglicized families in

Dublin and its neighborhood. Protestantism in Ireland at the death of Queen Elizabeth was represented by this small group. Hugh O'Neill, earl of Tyrone, and Rory O'Donnell, earl of Tyrconnell (Tyrconnell), harassed beyond endurance by the Dublin government, fled to the Continent in 1607. They were immediately proclaimed outlaws, and their patrimony, with that of all their followers, was declared forfeit to the crown. Thus immense tracts of land, including almost all of the counties of Donegal, Derry, Tyrone, Fermanagh, Cavan, and Armagh, were at the disposal of King James; Antrim and Down were afterwards added. James I proceeded to plant all these lands with English and Scottish settlers. This policy was carried into effect. Among the colonists the Scots were more numerous than the English. Though the teaching in Trinity College, Dublin, from its foundation, had been Calvinistic in tone, and the Established (state-supported) Church in Ireland was far more Calvinistic in spirit than its counterpart in England, the English and Scottish colonists failed to agree, so that Protestantism in Ireland faced the future in two divisions—Protestants with episcopacy and Protestants without episcopacy (Presbyterians).

The Irish insurrection of 1641 brought heavy losses to the Protestant Episcopal Church. Cromwell's settlement favored the Puritans, who were the predominant element in the new class of landowners. Charles II did something to restore the balance; the Protestant Episcopal Church was again established and richly endowed, but "Acts of Uniformity" failed to compel the Presbyterians to accept its system. They went their own way as Nonconformists (dissenters).

Once James II had been defeated, the Protestant Episcopal Church was restored by William and Mary to its position of pre-eminence. All the lords and commoners who increased the severity of the Penal Code belonged to it. Hence not only the Catholics, who formed four fifths of the population, were penalized, but also Presbyterians, who refused to receive the Sacrament according to the usage of the Established Church, were disqualified from holding positions of honor and trust under the crown. George Berkeley and Jonathan Swift are the two prelates of greatest distinction during the 18th century. At the union of the kingdoms in 1800 the Established Church of Ireland was united with that of England.

Disestablishment.—After emancipation, the Protestant Episcopal Church continued to levy tithes on an extensive scale for its own upkeep from Protestants and Catholics alike. The impost was naturally resented by the Catholics and led to conflicts called the "tithe war." A solution that proved to be satisfactory was found in 1838. Meanwhile the anomalous position of the Established Church in Ireland had been brought to the notice of the Parliament in Westminster. No steps were then taken; but the census of 1861, which showed that the number of Catholics in Ireland was 4,505,265, while Protestant Episcopalians numbered 693,357, Presbyterians 523,291, Methodists and other dissenters 76,661, opened the way to an unanswerable claim for disestablishment (severance of the relationship to the state). This was carried through by Gladstone in 1869. By the Irish Church Act of that year the Protestant Episcopal Church of Ireland was disestablished and disendowed, but given at the same time complete freedom to provide for its

own future and liberally compensated for the pecuniary losses which the change involved. Legislative and administrative power resides since 1870 in a general synod consisting of the two archbishops and 12 bishops, and a house of representatives elected from the clergy and the laity. In the six counties of Northern Ireland still attached to Britain, the Protestant Episcopal Church continues to exert great influence. In the 26 counties, which in 1921 became Saorstát Éireann (the Irish Free State), and in 1949 the Republic of Ireland, it retains its university (Trinity College) and its two cathedrals in Dublin; it is also facilitated by the Ministry of Education, and is protected by express "recognition" in the constitution.

The affairs of the Presbyterian Church are regulated by a general assembly, presided over by a moderator who is elected annually. It has (1951) 580 ministers, 567 congregations, and 510 manse. Like the Protestant Episcopal Church, the Methodists, the Society of Friends, and the Jews, it is recognized as a religious body that merits protection in the constitution of the Republic of Ireland.

Constitutional Status of Catholic Church.—In that constitution the Roman Catholic Church receives special recognition "as a guardian of the Faith professed by the great majority of the citizens." It is governed, under the pope, by four archbishops (one of whom, the archbishop of Armagh, primate of all Ireland, is generally a cardinal) and 23 bishops. A central theological university (St. Patrick's College, Maynooth) and the three colleges of the National University of Ireland (founded 1910) at Dublin, Cork, and Galway, supply its needs in the sphere of higher education. Its missionary activity in lands of English tongue and, more recently, in Africa and the East, is very extensive.

In the Republic of Ireland, statistics give (1951) 2,786,033 Catholics (94.3 per cent); 124,829 Protestant Episcopalians; 23,870 Presbyterians, 8,355 Methodists, and 3,907 Jews. In the six counties of Northern Ireland there are 428,290 Catholics (.33:5 per cent), 390,931 Presbyterians, 345,474 Protestant Episcopalians, and 55,135 Methodists.

IRISH LITERARY REVIVAL is the name customarily used to denote the literary activity in Ireland during the first half of the 20th century. Sometimes it is spoken of as the Celtic renaissance, a wider and looser term.

Background and Beginnings.—The Irish literary revival took place during the life span of William Butler Yeats (1865–1939), the Irish poet, and it would not be completely untrue to say that his work constituted most of what is spoken of as the Irish literary revival. The reasons for a renaissance taking place at one particular time more than at any other are rarely valid, because this presupposes that every renaissance must have a precise and scientific explanation. What really seemed to have happened at the time of the Irish literary rebirth was that Ireland, during a period of utter despair, suddenly found herself with an important poet in the family. The betrayal of Charles Stewart Parnell (q.v.), the uncrowned king of Ireland, crushed Ireland politically, and for the moment it seemed as if there was nothing Irishmen could do except look into their own hearts. For about 10 years after the death of Parnell in 1891 there was a lull in Irish politics, and it so happened that Yeats, a major poet, was beginning his career at this time and was able to take advantage of the silence to lay the foundation for his work later on. Without Yeats there would have been no literary revival. It is just that simple; but there were situations and influences, both political and emotional, which helped him in his work, and those are things that may be explained logically. To understand their significance, however, it is necessary to know something of the background of Irish literary and political history.

Since about 1170, the year the Anglo-Normans invaded Ireland, the population of the country has been divided into two classes: those who speak English and those who speak Gaelic. The English speakers became the ruling class and are referred to as the Anglo-Irish. England was generally regarded by the Anglo-Irish as the mother country and, to them, English literature was the only literature. It was to this class that George Farquhar, Oliver Goldsmith, Richard Brinsley Sheridan, Jonathan Swift, Oscar Wilde, and others belonged. The Gaelic speakers, though a majority, were regarded by the Anglo-Irish as mere natives, and although they produced a considerable literature in the Gaelic language, it remained virtually unknown to the Anglo-Irish until the middle of the 19th century. The Anglo-Irish writers were content to write in the English tradition because they were not aware of any other one in which they could write. The result was that though they did very fine work, there is little about it that can be considered distinctively Irish. Whether or not this was a defect is a question that does not concern us here; but there is no denial that their work was good, despite what some consider its un-Irish flavor.

Discovery of the Gaelic Tradition.—During the early years of the 19th century, hints that there was a Gaelic tradition began to filter into Anglo-Irish writing, and Thomas Moore's *Irish Melodies* (1804–1834), though written for an English public, were perhaps the first revelation of a distinctly Irish spirit in Anglo-Irish writing. Jeremiah Callanan (1795–1829) also caught something of the Irish spirit, and his verse shows the influence of the cadences of Gaelic versifica-

tion. Neither Moore nor Callanan, however, was completely aware of the Gaelic tradition.

Towards the middle of the century a few curious professors discovered Gaelic literature and undertook to translate many of the Gaelic sagas as a kind of scholarly exercise. In 1840, for instance, the Irish Archaeological Society was founded for the purpose of preserving Gaelic manuscripts and for their translation into English. The interest shown in Gaelic Ireland by this society was purely academic; its patrons were mostly members of the British aristocracy, and had they been able to foresee that their society was laying the foundations of what has since been regarded as a nationalistic literature, it is doubtful that they would have continued with their work. Other societies were formed later: the Celtic Society in 1845 and the Ossianic Society in 1853. These societies did good work and gave employment to at least three important scholars, John O'Donovan (1809-1861), Eugene O'Curry (1796-1862), and Standish Hayes O'Grady (1832-1915). These scholars translated most of the ancient Irish sagas and poems and published the result of their work in the journals of the societies. Many German scholars joined in the philological aspect of the work, the most notable being Johann Kaspar Zeuss, Rudolf Thurneysen, and Kuno Meyer. In 1853 Zeuss published a Gaelic grammar, *Grammatica Celtica*.

Men of creative genius such as James Clarence Mangan (1803-1849), Sir Samuel Ferguson (1810-1886), and Standish O'Grady (1846-1928) were excited by the discoveries of the scholars, they having been educated to believe that there was no literature outside of English literature. Immediately they began to rewrite the stories and poems of Gaelic Ireland in romantic fashion. Mangan and Ferguson were interested mostly in the poems, and some of their interpretive translations are among the finest poems in Anglo-Irish literature. Thomas Osborne Davis, Charles Gavan Duffy, John Mitchel, and a few other nationalistic politicians and journalists saw in the discoveries something they could use to further their political cause, and they wrote about it in their newspapers and preached it from their platforms.

But it was Standish O'Grady's translations of the sagas and his *History of Ireland* (1878) that had the greatest influence. O'Grady, believing in the sacredness of ancient tradition, saw that it would be disastrous to allow Ireland's past to be hidden away in scholarly publications. He decided to rewrite the stories in popular fashion. This he did brilliantly, not only in his *History of Ireland*, but also in *Cuculain and His Contemporaries* (1880) and other books.

Influence of Yeats.—All this happened at a peculiarly fortunate moment. Victorian literature was running its course, was becoming cliché and barren, and the Anglo-Irish writers were delightfully shocked when they found a new well of inspiration in Gaelic tradition. It was at this precise moment that Yeats was born. Yeats belonged to the Anglo-Irish class, and consequently did not understand a word of the Gaelic language. But his imagination was fired by O'Grady's translations, and on many occasions he acknowledged his indebtedness to him. George Russell (AE), in an introduction to the works of O'Grady (Dublin 1919), spoke not only for himself but for all the writers of the Irish literary revival when he wrote:

When I close my eyes and brood in memory over the books which most profoundly affected me I find none excited my imagination more than Standish O'Grady's epical narrative of *Cuculain* . . . With reference to Ireland, I was, at the time I read, like many others who were bereaved of the history of their race. I was a man who, through some accident, had lost his memory of his past, who could recall no more than a few months of a new life, and could not say to what songs his cradle had been rocked and what mother had nursed him, who were the playmates of childhood, or by what woods and streams he had wandered. When I read O'Grady I was as such a man who suddenly feels ancient memories rushing at him, and who knows he was born in a royal house, that he had mixed with the mighty of heaven and had the very noblest for his companions. It was the memory of race which rose up within me as I read, and I felt excited as one who learns he is among the children of kings. That is what O'Grady did for me and for many who were my contemporaries. . . . In O'Grady's writings the submerged river of national culture rose up again a shining torrent, and I realised as I bathed in that stream that the greatest evil one nation could inflict on another was to cut off from it the story of the national soul.

Having made this great discovery, Anglo-Irish writers were fired with interest in Irish literature and in the spirit that pervaded it. Many looked for guidance as to how they might make the best use of their discovery, and Yeats was fortunately there to direct the form it should take. Yeats perceived that Gaelic-speaking Ireland rarely read anything, but was always willing to listen, whether it be to a political speech or to a sermon. From his awareness of this fact rose the idea of founding a theater which would be truly representative of the real Ireland so ignored by his class. He would establish a poetic theater.

Having decided that a theater was what was needed, Yeats set about preparing the country for it. He felt that the Irish mind was too long enslaved and that a literary revival would not be possible until national pride was reawakened in the Irish people. He at once became a vigorous nationalist and developed a deep personal regard for John O'Leary, the Fenian leader. He also met Maud Gonne, a violent nationalist, fell in love with her, and for her wrote *The Countess Cathleen* (1892).

Literary Societies.—It seemed to Yeats that Ireland was not quite ready to receive him, so he moved to London, where he drifted for a time into the circle of the Aesthetes. O'Leary and his other friends, fearing that he was in danger of selling his soul for an empty aestheticism, begged him to return. He did not do so immediately, and in 1891, with two other Anglo-Irish writers, Thomas William Rolleston and John Todhunter, founded the Irish Literary Society in London. This society attracted to it most of the other Anglo-Irish writers who were living in London, including Katharine Tynan, Alice Milligan, William Larminie, and Stopford Brooke. All of these writers were extremely minor, but they were almost carried into significance by the influence of Yeats and the romanticism created by O'Grady and the rest. In the same year Yeats went over to Dublin and established there a similar society, The National Literary Society. John O'Leary was its first president, and its members included Douglas Hyde, George Sigerson, and Standish O'Grady.

Gaelic League.—The purpose of these societies was to give an opportunity to a new generation of critics and writers to denounce the propagandist verse and prose that had gone by the name of Irish literature and to substitute for it certain neglected Irish writers such as Sir Samuel Ferguson, Standish O'Grady, and James Clarence

Mangan. The society had no political affiliations. From this society sprang the Gaelic League, founded in 1894 by Douglas Hyde (q.v.). Hyde's idea was to revive the Gaelic language, which was then dying, as the spoken language of the whole country. Yeats did not think it worth his own while to learn the Gaelic language, but he supported the Gaelic League (before it became a propaganda machine) because he considered it an effective means of awakening the Irish people to a consciousness of their history and tradition. Douglas Hyde, though mostly a pamphleteer in favor of the Gaelic language, did some writing that had a significance for the Irish literary revival. His *Love Songs of Connacht* (1894), translations from the Gaelic, helped to set the mood for writers of the revival movement. His *Literary History of Ireland* (1899) was also a valuable contribution.

Irish Literary Theatre.—The literary societies of London and Dublin created an audience for Yeats and his ideas. In 1889 Yeats published *The Wanderings of Oisín*, and during the 1890's he was writing the lyrics which formed the volume, *The Wind Among the Reeds*. In 1893 he published a collection of fairy lore which he entitled *The Celtic Twilight*. The following year he had his poetic play, *The Land of Heart's Desire*, produced in London.

But despite his success in London, Yeats could see that only in Ireland could he do the things he wished to accomplish; so, with the help of George Moore, the novelist, and Edward Martyn, a wealthy Irish landlord and minor playwright, he went to Dublin and produced his own play, *The Countess Cathleen*, and Martyn's *The Heather Field* at the Antient Concert Rooms in 1899. To Yeats' amazement his play was received with boos and hoots because some saw in it a theological heresy. When he recovered from the surprise, Yeats accepted the insults as the traditional greetings for a messiah, and, from then on, always treated the mob, whether it be English, Irish, or American, with violent disdain.

He named his dramatic company The Irish Literary Theatre, and was back in Dublin the following year with another series of plays. After producing the third series of plays in Dublin, in 1901, he rid himself of George Moore and Edward Martyn and associated himself closely with Lady Augusta Gregory, a friend of his from Coole, in the west of Ireland. Yeats had not given up the idea of founding a poetic theater in Ireland, and in 1902 he had another play which he had written, *Cathleen Ni Houlihan*, produced by a group of actors led by the Fay brothers, Willie and Frank. He formed another society, the Irish Dramatic Company, consisting of himself, Lady Gregory, the Fay brothers, and John Millington Synge, an Irish writer whom he had discovered in a Paris garret. It was Yeats' ability to discover genius that made an Irish literary revival possible.

Synge and Lady Gregory.—When Synge returned from Paris, on Yeats' urging, he first went to live among the gypsies in Wicklow and, later, among the inhabitants of the Aran Islands, off the west coast of Ireland. The peasants on the Aran Islands spoke the Gaelic language but also knew a little English. Synge quickly absorbed the life of these primitive people and wrote plays about them. *Riders to the Sea* is a one-act tragedy about an island woman who has lost all her sons to the sea; while Irish, it

has many of the elements of Greek tragedy. *In the Shadow of the Glen* was disliked because Synge tells of an unfaithful Irish wife. *The Playboy of the Western World* raised an even bigger storm. In this play Synge tells how the peasants in a village in the remote west of Ireland hide a young fellow (the Playboy), who claimed that he was fleeing from the police because he had killed his Da (father) with a blow of a loy (long, narrow spade). This was too much for an Irish patriotic audience, and they rioted at the first performance because they considered the play an insult to Irish character by suggesting that these peasants would condone a murder. This, they claimed, was not the kind of play that should be put on by a theater that claimed to be national. Yeats' policy, however, was not to give the public what they liked but rather what he thought was good for them, so he called in the police and continued the play under heavy guard. This was the final insult from the point of view of Irish patriots, and they avoided Yeats and his plays in the future. Yeats, however, had a decided plan of action and he carried on, despite all opposition, to give Ireland a literature worthy of her tradition. Synge died in 1909, his death being a great loss to the Irish literary revival.

Lady Gregory (1859-1932), too, began to write plays under Yeats' influence and direction. She is best known for her comedies, *Spreading the News*, *Hyacinth Halvey*, *The Rising of the Moon*, and many others. She also translated many plays from the French and was interested in the folklore of Ireland. Hence her books *Cuchulain of Muirtheimne* (1902), *Poets and Dreamers* (1903), *Gods and Fighting Men* (1904), *A Book of Saints and Wonders* (1906). Lady Gregory wrote her plays in dialect, and the language of the Irish literary revival is sometimes referred to as the Kiltartan dialect, a name taken from the parish where Lady Gregory lived.

Abbey Theatre.—In 1904 Miss Annie Elizabeth Fredricka Horniman, a wealthy English lady, presented Yeats with a small theater in Abbey Street, Dublin, named the Abbey Theatre. From 1904 onwards the Abbey Theatre was the center around which the literary revival in Ireland moved. Now that he had a theater of his own, Yeats put into effect his theories and ideals. First of all it would be a poetic theater where the imaginative mind of Ireland would find expression. It was to be a place almost as sacred as a church, and those who come there must not expect vulgar entertainment but must come rather to listen to a poet explain his vision. Above all, there was to be no place in it for politics, because politics presuppose defense and argument, and a continual apology makes the mind barren and kills intellectual innocence. He wanted the plays performed there to be literature and to have style. Furthermore, the English language, according to Yeats, had worn itself out during Victorian times, and his theater needed a language that was fresh. The Gaelic language would be acceptable, but none of the literary revivalists knew that language. The language Yeats finally adopted was the dialect of English spoken by the peasants from the west of Ireland. Although these peasants spoke English, they thought first in Gaelic, and the result was a fresh and unspoiled language with personality. This is the language used in the plays of Synge and Lady Gregory. As found in the plays, it is

not completely authentic, but it has a quaint, unreal, dreamy flavor; hence the slightly derogatory term sometimes applied to this movement—the Celtic mist.

Yeats also had fixed principles on acting, which was to be statuesque and unobtrusive—as fitting for a drama which was to be poetic and ritualistic. Yeats disliked a large audience in his theater, and the plays frequently infuriated those who came, especially when it was thought that the ideas expressed ran counter to popular national sentiment. Sometimes it appeared to the politicians that Yeats was an enemy of Ireland, but he refused to be dictated to and followed his own ideals to the end. The result of this policy was that he established a literature of the highest integrity and which expressed the Irish spirit and tradition.

Sean O'Casey.—Yeats discovered not only Synge but also another major dramatist—Sean O'Casey. O'Casey was born in the poverty-stricken slums of Dublin. He received little formal education, but he read widely and attended the Abbey Theatre whenever he could afford the entrance price of sixpence. He submitted a play to the Abbey, but it was rejected with some encouraging remarks. The next play he sent in, *The Shadow of a Gunman* (1923), was accepted and was an immediate success. Like all his early plays, this one was centered around the Dublin slum-dwellers. It is realistic, but is lifted to an imaginative level; it is also extremely amusing. Then followed his greatest play, *Juno and the Paycock* (1924), also about life in the slums of Dublin. The characterization is brilliant. Lady Gregory said that the play reminded her of Tolstoy, and other critics have described it as the greatest play since *Hamlet*. O'Casey's next play, *The Plough and the Stars* (1926), caused a riot in the theater because some oversensitive patriots thought it an attack on Irishmen who fought during the Easter Rising of 1916. The dialogue in these early plays by O'Casey is the most authentic Irish dialect of all the plays of the Irish literary revival. Shortly after the production of *The Plough and the Stars* O'Casey went to live in London, and though he subsequently wrote many plays they can hardly be said to belong in spirit to the Irish revival.

Other Dramatists.—Yeats was also responsible for the discovery of many other dramatists, of whom Lennox Robinson and T. C. Murray are the most important. Murray is best known for his plays *Birthright* (1910) and *Maurice Harte* (1912), which treated of Irish peasant life in a lyrical fashion. Robinson wrote many plays, but is best known for *The Far-off Hills* (1928), *Drama at Innis* (1933), and *Church Street* (1934). Robinson wrote realistically of the broken-down Anglo-Irish aristocracy. Other plays worth mentioning as belonging to this period would be St. John Ervine's *Mixed Marriage* (1910), and Paul Vincent Carroll's *Shadow and Substance* (1937). This play by Carroll was the last play of any consequence performed at the Abbey Theatre before the death of Yeats and the ultimate collapse of the Abbey as a theater of integrity.

Yeats the Poet.—Yeats was not a great dramatist and, though he wrote plays that were memorable, he will be remembered primarily as a poet. His early verse is strongly influenced in subject by pre-Christian Ireland and in form by the aesthetic and symbolistic movements in Eng-

land and France. This is especially true of his early collection of poems, *Poems* (1895), and *Wind Among the Reeds* (1899). In his later verse he outgrew his "Celtic twilight" mood as in *The Wild Swans at Coole* (1917); there we find him stretching for a more eternal subject. *The Tower* (1927) and *The Winding Stair* (1929) contain much of his best and most vigorous poetry. Yeats also wrote *The Celtic Twilight* (1893), a collection of folk stories.

George Bernard Shaw.—While Yeats was carrying on a literary revival in Ireland, Bernard Shaw (1856-1950) was engaged on one of his own in England. Although he did not write in the "Celtic twilight" tradition, he undoubtedly must be regarded as a major figure in the Irish literary revival. He was an intellectual as opposed to an imaginative writer, and his clear views and pungent satire acted as an antidote to those writers who frequently drifted out of the Celtic mist into a Celtic fog. He was born in Dublin, and all through his life that city remained his emotional home. He was employed as a clerk in a realtor's office for a short while, but retired from it and went to London to make his way as a writer. His early years in London were difficult, and although he wrote five novels he could not find a publisher for them. He was a successful music critic for a while. Then he became interested in play writing and discovered there one of his greatest talents. For over 50 years thereafter he wrote plays of all types—histories, comedies, sketches, farces. He ignored conventional plots, and many of his plays might be described as brilliant conversational pieces. Some of his best known plays are: *Candida* (1895), *John Bull's Other Island* (1904), *The Doctor's Dilemma* (1906), *Pygmalion* (1912), *Saint Joan* (1923), the last considered by many to be his best play. A large number of his plays were produced at the Abbey Theatre in Dublin despite the fact that Yeats disliked plays that were not founded on a poetic idea. Shaw wrote brilliantly on every topic, and was an entire Irish literary revival in himself.

George W. Russell and Others.—Even in Ireland, Yeats was not the only influence though he was by far the greatest. George W(illiam) Russell (1867-1935), better known as AE (Æon), though not a great poet, gathered around him many writers of talent. He was a mystic, economist, painter, and essayist as well as a poet. He was born in County Armagh but moved to Dublin at an early age, and was a student of the Metropolitan School of Art before he was 13 years old. There he met Yeats, and through him became interested in theosophy. His *Homeward: Songs by the Way* (1894) attracted wide attention. In 1897 he joined the Irish Agricultural Organization Society, and in 1906 became editor of *The Irish Homestead*, journal of that society; in 1923 *The Irish Homestead* amalgamated with *The Irish Statesman*, with Russell remaining as editor. *The Irish Statesman* was unique as a magazine in that it was read by intellectuals in most countries, as well as by Irish farmers. AE attracted to his magazine all the best writers, and all of them felt honored when their writings appeared in it. AE's home in the Dublin suburbs was the meeting place of most of the writers associated with the Irish literary revival.

AE had a religion all his own, which some wit described as AEtheism; it was a mixture of

Irish mythology and Hindu philosophy. He sought in the Irish mythology for hints of an ancestral lore identical with that of the Eastern sages. This mystical religion influenced his contemporaries, and contributed to the "Celtic mist." AE expounded his religious philosophy in *The Candle of Vision* (1918), and his political idealism in *The Interpreters* (1920). His collected poems were published in 1913, but he wrote much that was of interest later on, especially *The House of the Titans and Other Poems* (1934). Perhaps because he was a lesser genius than Yeats, he was easier to approach and therefore had a greater influence, more personal if less profound than Yeats'.

Minor writers of the movement who gathered under AE's cloak were, Alice Milligan, Eva Gore Booth, Padraic Colum, Ella Young, and Seumas O'Sullivan. Although these minor writers may have failed as poets of consequence, they served as a necessary backdrop for the literary revival. Of the minor writers, Francis Ledwidge (1891-1917), showed most promise, but his career was cut short when he was killed in action in Flanders; his two books of poems, *Songs of the Field* (1915) and *Songs of Peace* (1916), had a magic quality and in form were heavily influenced by the Gaelic poetic mode.

Before *The Irish Statesman* became defunct in 1930, AE introduced in its pages poets who, if they did not belong to the Irish literary revival proper, at least developed from that stream and initiated a secondary revival in Irish poetry and letters. Frank O'Connor (born in 1901), though now known only as a story-teller, began as a poet in *The Irish Statesman*. Frederick Robert Higgins (1896-1941) was another; he came from Meath, Ledwidge's county, and his verse has much in common with that of Ledwidge. He wrote of the fields in a lyrical fashion, but his verse lacks intensity and that inner sincerity which is essential to poetry. *Dark Breed* appeared in 1927, *Arable Holdings* in 1933, and *The Gap of Brightness* in 1940. Higgins was managing director of the Abbey Theatre for a while before he died.

Patrick Kavanagh (born in 1904) also began as a poet in *The Irish Statesman*, but after the death of AE he disentangled himself from those influences associated with it and wrote freshly and originally about the Irish countryside; of his books of verse, *A Soul for Sale* (1947) is the most significant. He is also the author of *The Green Fool* (1938), a prose work which is a mixture of autobiography and fiction. *Tarry Flynn* (1949) is a novel on the frustration in Irish country life; the romanticism of the Celtic twilight is cast aside for a less charming but more sincere approach.

Prose Writers.—Although poetry and drama predominated during the Irish literary revival, the prose writing of the period is also significant. The novelists, like the playwrights, broke away from the 19th-century tradition, which usually displayed the Irishman as a wild, screaming lunatic who carried a clay pipe in his hat and a shillelagh in his hand.

George Moore (1852-1933) was the most important prose writer of the early years of the movement. He was born in Mayo, but lived for many years in Paris and in London. He was deeply influenced by Gustave Flaubert and Honoré de Balzac, and is a brilliant stylist. He wrote many realistic novels, the most notable

being *Esther Waters* (1894). He has been called the first realistic novelist since Daniel Defoe. In 1900 he assumed a nationalistic pose and returned to Ireland, but his nationalism was too flamboyantly insincere and only caused embarrassment to those supporting what they cryptically called "the cause" (meaning the cause for Irish political independence). Yeats described Moore as "preposterous and ungovernable." While in Ireland, Moore wrote a series of short stories of Irish life which were published under the title *The Untilled Field* (1903); they were translated into the Gaelic language also. Moore's greatest contribution to the Irish literary revival was his trilogy, *Ave* (1911), *Salve* (1912), and *Vale* (1914). These books give a fascinating and slightly comic account of the Irish literary revival and of all those associated with it; they are brilliantly satiric, and should be read by anyone interested in knowing more of the Irish literary activity. Moore was a mocker and a blasphemer, and he laughed to the very end. On his instructions, his body was cremated and the ashes deposited in a hole on the top of a mountain on his estate in the west of Ireland. AE preached a panygeric on that occasion in which he pointed out that Moore "loved the land if he did not love the nation."

James Stephens (1882-1950) began writing as a poet, but he suddenly achieved fame as a prose writer in 1912 with the publication of *The Crock of Gold*. This book is unique and difficult to label. It is a brilliant fantasy, resembles a novel in form, and has an Irish background; it has been universally recognized for a long time as a classic. Some of his other books of prose are *The Charwoman's Daughter* (1912) and *The Demi-Gods* (1914). It has been remarked that his prose is closer to poetry than much of his verse. John Millington Synge, the playwright, wrote two volumes of travel-sketches, *The Aran Islands* (1907) and *In Wicklow, West Kerry and Connemara* (1910) which are interesting for their style and for their description of Irish life. Edith Anna O'Enone Somerville and Martin Ross (Violet Florence Martin) collaborated in a book entitled *Experiences of an Irish R.M.* (1899) which is considered by some to be very amusing.

Seumas O'Kelly wrote a number of plays, including the very sentimental *The Shuiler's Child* (1909), but his best work is the short story, *The Weaver's Grave* (1920), which describes the peculiar fear of the Irish peasant that he might, in error, be buried in someone else's grave. Daniel Corkery (born in 1878) wrote some good realistic, though quiet, stories of Irish country life, including *The Threshold of Quiet* (1917) and *The Wager and Other Short Stories* (1950); he is also the author of *The Hidden Ireland* (1925), a study of Gaelic Ireland in the 18th century. Lord Dunsany (born in 1878) is worth mentioning for his fantasies: *The Gods of Pegana* (1905), *Time and the Gods* (1906), *The Sword of Welleran* (1908), *Dreamer's Tales* (1910), and many others. His fantasies, however, lack the high imaginative qualities of those by James Stephens. Flann O'Brien (1911-) is the author of a notable fantasy, *At Swim-two-birds* (1939).

Joyce.—James Joyce (1882-1941), though he disavowed any connection with the Irish literary revival, is nevertheless generally regarded as a distinct part of it.

But I must not accounted be
One of that mumming company

he wrote of Yeats and the Abbey Theatre. He was born in Dublin and attended the Jesuit college of Clongowes Wood. In 1907 he published a little book of lyrics entitled *Chamber Music*. Seven years later *Dubliners*, a book of short stories about Dublin life, was published. It showed that its author had a sharp perception for the nuances of Dublin dialect, which he used with skill. The cold style was learned from Gustave Flaubert, and it was particularly suited to his Thomistic temperament. *A Portrait of the Artist as a Young Man* which followed in 1916 is also about Dublin life, but is slightly scholastic in tone. Joyce, unable to make a living in Dublin, went abroad and lived in Trieste and Paris while he worked on a new book, *Ulysses* (1922). This was a novel of Dublin life, and though it is extremely long, the action takes place all in one day. Joyce employed in this novel a new technique which has been described as "the stream of consciousness." By this is meant that he records the conscious and sub-conscious thoughts of his characters and allows them to weave in and out of the story in what might appear to be a disorder. This new method of novel writing caused a sensation and it was much discussed in intellectual societies in Paris and America. The book is still banned in many countries for its alleged obscenity. The hero of *Ulysses* is Leopold Bloom, a Jew, and Joyce intended that he represent the human race. The dialogue is realistic and alive. *Finnegans Wake* (1939) is even more obscure than *Ulysses*. It is highly praised by those who profess to understand it, and by others it is condemned as the ravings of a sick mind. Joyce had no successful imitators, and AE said of him that he was a cistern and not a fountain.

Novelists.—Liam O'Flaherty, Peadar O'Donnell, and Frank O'Connor are all realists. Liam O'Flaherty was born on the west coast of Ireland. His early short stories describing the life lived in that area have both freshness and vigor; his realism is always touched with a lyricism which lifts his stories to an imaginative plane. He is the author of many novels and books of short stories, including *Thy Neighbour's Wife* (1924), a novel; *Spring Sowing* (1926), stories; *The Informer* (1926), a novel; *Famine* (1937); *Short Stories of Liam O'Flaherty* (1937); and *Two Lovely Beasts* (1948). He also wrote short stories in the Gaelic language. Peadar O'Donnell was born in Donegal, among the Gaelic-speaking peasants of that area. His novels, which portray the life of the poverty-stricken peasants struggling to survive, include *Islanders* (1925), *Adriagoole* (1928), *The Knife* (1930), and *On the Edge of the Stream* (1934). He had a passion for justice, and this caused him to devote much of his time to humanitarian work on behalf of the Donegal migrant laborers.

Frank O'Connor was born in Cork about the year 1901. He fought in the struggle for Irish political freedom in the early 1920's, and his first book of stories, *Guests of the Nation* (1931), told of his experience as a rebel. He came under the patronage of AE, who brought him to Dublin and arranged a job for him as librarian. Most of his early work, which is full of vitality, appeared first in *The Irish Statesman*. In 1932 he published his first novel, *The Saint and Mary Kate*. Those that followed included

The Wild Bird's Nest (1932), *Bones of Contention* (1936), and *Selected Short Stories* (1946). He wrote two plays while he was a director of the Abbey Theatre and translated many poems from the Gaelic, including Merri-man's *The Midnight Court*. The scene of most of his stories is laid in Cork. His early stories are his best work.

The autobiography in four volumes of Sean O'Casey, the playwright, is an important contribution to Irish prose writings: *I Knock at the Door* (1939), *Pictures in the Hallway* (1942), *Drums under the Windows* (1945), and *Inisfallen, Fare Thee Well* (1949). Of the four volumes the first, which is probably the best, describes O'Casey's childhood and the Dublin life of the time; the style is vigorous and the point of view clear. *Drums under the Windows* is unfortunately influenced to its detriment by the style of James Joyce. *Inisfallen, Fare Thee Well* discusses, among other things, his own relation to the Irish literary revival.

Essayists.—The essay form was widely cultivated during the period under review. Almost every Irish writer wrote essays. Yeats is probably the most important essayist, because he was the most important writer. Many of his early essays appeared in *Bealtaine* and *Samhain*, the periodicals issued by the Irish Literary Theatre. Many of his books of prose consist of essays—such as *The Cutting of an Agate* (1912), *The Trembling of the Veil* (1922), and *Dramatis Personae* (1936). Yeats was a brilliant essayist, and though he had a clear style, he concentrated more on saying something than on the means of saying it.

AE also wrote essays of a high order of merit, most of them appearing in *The Irish Statesman*. The essays of Shaw on every conceivable topic are so well known that it would serve no purpose to discuss them here. George Moore wrote many delightful essays on literature, art, and music. While they are noted more for their style than for their content, there are critical comments and ideas in them that have more than passing value. John Eglinton (William Kirkpatrick Magee) concentrated on the essay form alone; the fact that he was a close friend of Moore is sufficient to indicate that his attitude was sceptical, detached, and ironical. Eglinton set himself the task "to introduce new unassailable ideals of nationality, to sink the wells of thought beneath the barren surface of tradition, and to bring Ireland into political and spiritual unity." Although a definite part of the Irish literary revival, he had, like Moore, little sympathy with it. He is a fine stylist, and Yeats described his writings as full of "orchestral harmonies." However, he had little to say that was original, and he took his stand in favor of cosmopolitanism in literature rather than nationalism. He came from the north of Ireland, and perhaps this had some influence on his point of view. His books include: *Two Essays on the Remnant* (1896), *Pebbles from the Brook* (1901), and *Anglo-Irish Essays* (1917). Ernest Augustus Boyd was an essayist and critic. Two of his books are important: *Ireland's Literary Renaissance* (1916) and *The Contemporary Drama of Ireland* (1918).

Ballads.—Ballad writing was popular during the period, and many of the ballads, written anonymously, will remain permanently in Irish literature. Some of the ballad writers whose

names we know are: Alfred Perceval Graves, author of *Father O'Flynn*, Patrick Joseph McCall, who wrote *Irish Fireside Songs*, and Francis Arthur Fahy, author of *The Ould Plaid Shawl*.

Bibliography.—O'Grady, Standish, *Early Bardic Literature* (1879); Zimmer, H., *The Irish Elements in Mediaeval Culture* (1891); Duffy, Sir C. G., Sigerson, G., and Hyde, D., *The Revival of Irish Literature*, addresses (1894); Hyde, D., *A Literary History of Ireland* (1899); Yeats, W. B., *Synge and the Ireland of his Time* (1911); Brown, S. J., *A Guide to Books on Ireland* (1912); O'Donoghue, D. J., *The Poets of Ireland* (1912); Gregory, Lady I. B., *Dramatis Personae* (1936); Hone, J. M., W. B. Yeats (1943); Kavanagh, P., *The Story of the Abbey Theatre* (1950).

PETER KAVANAGH,
Author of "*The Irish Theatre*" and "*The Story of the Abbey Theatre*."

IRISH LITERATURE IN THE ENGLISH LANGUAGE. This phrase is used to indicate the writing of those persons who, though born in Ireland, wrote exclusively in the English language and, generally speaking, directed their writing toward an English public.

Until the mid-19th century the majority of the Irish people spoke only Gaelic, and only a very small, but important, minority spoke English. The first contingent of Anglo-Norman invaders entered Ireland in 1169; the towns were quickly seized by the Strangers (as they were called), and an English-speaking colony was established. Strengthened by succeeding expeditions in 1170 and 1171, the English-speakers became the ruling class and generally were disliked by the native Irish. After some generations the early English settlers became more Irish than the Irish—as one writer put it; and they, in turn, resented all subsequent invasions by the English. However, they always regarded England as the mother country, in much the same manner as the Irish-Americans regard Ireland. Until early in the 20th century the English-speakers never really amalgamated with the native Irish or Natives (as they called them); consequently reference is usually made to them as the Anglo-Irish.

Extreme Irish nationalists sometimes speak disparagingly of the Anglo-Irish and accuse them of being un-Irish. This is a narrow view based on the false notion that only those who speak flatteringly of a country can justly claim to be its citizens. In fact, it was precisely because the Anglo-Irish were not encumbered with a false sentiment for Ireland that they wrote so well and added so much luster to Irish literature. They wrote, it is true, for an English public, but, because they were Irish and living in Ireland, they necessarily must have had Irish emotions. Anglo-Irish writers could not escape, even if they had so wished, the Irish color and attitude. But even if no Irish attitude were obvious in their writing, there would be nothing requiring apology. What really mattered is that they wrote well.

The contribution to English literature by Irish writers using the English language is greater than one may assume from a casual glance. Immediately the names of the best Irish

writers come to mind—Jonathan Swift, Oliver Goldsmith, Richard Brinsley Sheridan, Oscar Wilde, Bernard Shaw—but there are many others whose writing has added vigor to what is called English literature. It is possible to exclude the Brontës (whose father was Irish) and William Congreve (who spent the most impressionable years of his life in Ireland) and yet to have a very impressive list. There is no branch of English literature which Irish writers have not invaded and at times have dominated. It is said sometimes that Irish literature in English began with Swift (1667–1745), but the inaccuracy of this statement is demonstrated by St. John Seymour in his book *Anglo-Irish Literature, 1200–1582*. There he quotes a poem entitled *The Land of Cokaygne* (written in the last half of the 13th century) in which the friars of Kildare are satirized because they appear to have made, in dumb show, theatrical representations of some of the incidents in the Bible. So quick were the Anglo-Irish to adopt the drama, and so great is their accomplishment in this branch of literature alone, that it may be best to discuss first their contributions to drama.

DRAMA

Beginnings of the Drama Form.—The earliest reference to a dramatic entertainment occurring in Ireland is in a document consisting of 17 constitutions of a Dublin provincial council which Archbishop Thomas Minot held at Kilkenny in 1366. According to the seventh constitution, which is entitled *Constitutio ne mercata in ecclesiis vel earum acris seu cimiteriis teneantur, nec negociaciones seculares exerceanntur*, priests are ordered to forbid "such theatrical games and frivolous spectacles, by which the churches are dishonored; and the aforesaid priest must warn them, under suspension, and order them in future to abstain from such acts and to cease from them under pain of greater excommunication."

It is clear from this canon that in Ireland at that early period plays of some kind were acted both in the churches and in the cemeteries. We know that it was customary in both England and France at the same period for plays to be acted inside churches, and that ecclesiastical authorities legislated against the practice. In Marsh's Library, Dublin, is a copy of a religious processional, written in the 14th century and owned in the 15th century by the Church of St. John the Evangelist, Dublin. It is the usual type of processional, describing the coming of the three Marys to the tomb of Christ, but written as a play. There is, however, no conclusive evidence that it was performed in Ireland. Again, *The Pride of Life* (1343), of which the manuscript was discovered in Dublin, is the earliest known morality play in the English language. The texts of two other religious plays of an early period, *The Play of the Sacrament* and *Abraham's Sacrifice*, are preserved in Trinity College Library, Dublin. It is most likely that these plays were performed in Ireland.

That medieval pageants were popular in Dublin during the 15th century is attested by the *Chain Book of the City of Dublin*, which gives an exact account of the pageant held in 1498. But the first really important dramatic performance in Ireland occurred at Kilkenny on Aug. 20, 1553, when two plays, still extant, written by John Bale (1495–1563), the Protestant bishop

of Ossory, were acted at the Market Cross. With some truth Bale may be described as the father of Anglo-Irish drama, although he was an Englishman by birth and by breeding. He was a prolific writer of moralities, all of which are violently anti-Catholic. His best-known play is entitled *Kynge Johan* (written before 1548). Bale's importance to Irish dramatic development may easily be underestimated because of his brief stay in Ireland—less than a year. Since he introduced to Ireland plays of some topical significance, it may be claimed that these plays had an influence on Irish dramatic literature.

Early Playwrights.—Ireland's first public theater was built by John Ogilby (1600–1676), a Scot, in Werburgh Street, Dublin, some time between 1634 and 1638; and James Shirley (1596–1666), the English dramatic poet, was invited to Dublin to write plays specially for the new theater. Shirley chose an Irish theme for one of his plays, *St. Patrick for Ireland*. This play treats the story of St. Patrick's conversion of the Druids; John Eglinton says of it that "it enables us, far better than a good many of the acknowledged sources of the period, to realise how the Anglo-Irish felt towards their country on the eve of the rebellion." Shirley really set the standard for Anglo-Irish drama, and very soon Anglo-Irish writers were following his example. Ireland gave four playwrights to English literature before 1660: Sir John Denham (1615–1669), Richard Flecknoe (d. 1678), Henry Burnell (fl. 1641), and Henry Burhead (fl. 1645). It is doubtful whether Denham should be claimed as an Anglo-Irish writer for, as an English historian recorded, "before the Foggy Air of that Climate could influence or adulterate his Mind, he was brought from thence." Flecknoe, who wrote many plays, was a very bad poet, and is mentioned with contempt by Pope in the second line of the *Dunciad*. Burnell, it is claimed, was pro-Irish, but his one surviving play, *Landgartha*, shows no trace of it. Henry Burhead's *A Tragedy of Cola's Furie or Lirinda's Miserie* treats of the insurrection of 1641 from the Irish point of view. During the 17th century the Jesuits produced Latin plays in Ireland.

Irish Dramatists.—After the Restoration (1660) Anglo-Irish writers took a very active interest in the English stage. Roger Boyle, earl of Orrery (1621–1679), was the first to introduce the heroic play to England. Thomas Southerne (1660–1746) was highly regarded as a playwright; in his *Oroonoko*, a very popular play, he attempts to expose the evils of the slave traffic.

George Farquhar (1678–1707), though hardly equal to the Irish-educated William Congreve (1670–1729), was scarcely less significant than he. Farquhar's plays were less refined than Congreve's, but they were more human. There is a Rabelaisian gaiety about them which, if not typically Irish, is certainly not English. Farquhar's is real critical comedy. He disliked pretense, and in his plays he took great pleasure in exposing the conventional affectations and deceptions of certain ranks of society and, especially, of the English army officer. Farquhar anticipated the modern domestic drama. He set an example for his contemporaries, who unfortunately were not great enough to profit by it. His best-known plays are *The Recruiting Officer* and *The Beaux's Stratagem*.

Another Anglo-Irish playwright of the period

was Susanna Centlivre (1667–1723). She is best known for her plays, *The Busy Body* and *The Wonder!* Although she was not a great dramatist, William Hazlitt thought highly of her. "Her plays," he wrote, "have a provoking spirit and volatile salt in them which will preserve them from decay. *The Wonder!* and *The Busy Body* are properly comedies of intrigue. Their interest depends chiefly on the intricate involution and artful denouement of the plot, which has a strong tincture of mischief in it, and the wit is seasoned by the archness of the humour and sly allusion to the most delicate points."

Although Richard Steele (1672–1729) is remembered only as an essayist, his plays were at least a minor addition to English dramatic literature; their weakness lay in his sentimentalism. *The Funeral* is the most readable among them; the passage in which he satirizes the undertaker is quite amusing. Hazlitt thought little of Steele as a dramatist, and characterized his plays as "rather homilies in dialogue, in which a number of very pretty ladies and gentlemen discuss the fashionable topics of gaming, of dueling, of seduction, of scandal, etc., with a sickly sensibility that shows as little hearty aversion to vice as sincere attachment to virtue." Steele's *The Conscious Lovers* was a popular success.

Other Anglo-Irish dramatists of this period were Owen Swiney (b. 1680), Samuel Madden (1686–1765), William Phillips (d. 1734), Charles Coffey (d. 1745), Michael Clancy (d. 1760), Charles Molloy (d. 1767), and Henry Brooke (1703–1783).

18th-Century Playwrights.—Oliver Goldsmith (1728–1774) and Richard Brinsley Sheridan (1751–1816) are undoubtedly the best-known dramatists who wrote in English during the 18th century. Both were Irishmen. Goldsmith contributed to every major phase of English literature; he was a poet, a novelist, a dramatist, and an essayist. As Samuel Johnson (1709–1784), to whose circle he belonged, said of him, "he touched nothing that he did not adorn." He wrote two plays, *The Good Natur'd Man* and *She Stoops to Conquer*; he is also the author of a farce called *The Grumbler*. It would not be difficult, if one so wished, to indicate the Irish influence in Goldsmith's writing, especially in *She Stoops to Conquer*, whose boisterous good humor and ridicule of the sentimentalism characterizing the contemporary comedy of tears are undoubtedly facets of the Irish temperament. *She Stoops to Conquer* could have been written only by an Irishman; it is full of that reckless, devil-may-care spirit peculiar to the Irish. Goldsmith, while essentially Irish, does not exhibit intentionally the characteristics which lead to stage Irishism, but passively allows his Irish nature and spirit to express themselves.

Sheridan, like Goldsmith, is so universally known for his contribution to English literature, that it is unnecessary to discuss his work at any great length here. His *The Rivals* and *The School for Scandal* are still acted and enjoyed. Although he did not equal Farquhar for imagery of language or Congreve for style, Sheridan is nonetheless a dramatist of power. In one thing at least he excelled Congreve and Farquhar—he held the follies of his age up to delightful ridicule. The equal of *The Rivals* and *The School for Scandal* as pieces of satirical comment on the mannerisms of middle-class society have never been written before or since. Leigh Hunt

describes him as "a Shakespeare without a heart"; and Hazlitt said of him that "among the comic writers of the last century he shines like Hesperus among the lesser lights." Like most Irish writers, he spent most of his life in England and wrote for an English public.

Arthur Murphy (1727-1805), author of 21 plays and frequently compared by scholars with Sheridan, was a member of Johnson's circle. His best-known play is *The Grecian Daughter*. Essentially a sentimentalist, Murphy tried to write in the true comic vein and, because he attempted the compromise, he failed as a writer. His plays, however, are significant in the history of Anglo-Irish drama.

Hugh Kelly (1739-1777), a great friend of the English actor David Garrick (1717-1779), is the author of *False Delicacy*, a sentimental play which was a great popular success. Kelly was very conscious of Ireland, and wrote *The School for Wives* "in defence of Law and Irishmen." He attempts the Irish idiom, but the result is neither authentic nor artistic.

John O'Keeffe (1747-1833), the popular writer of ballad-opera, romantic comedy, and farce, was born in Dublin. He is the author of at least 77 dramatic pieces, many of which are still remembered. Hazlitt says of O'Keeffe: "He might well be called our English Molière . . . In light, careless laughter, and pleasant exaggerations of the humorous, we have had no one equal to him. There is no labour or contrivance in his scenes, but the drollery of his subject seems to strike irresistibly upon his fancy, and run away with his discretion as it does with ours." His best dramatic piece is *The Agreeable Surprise*. O'Keeffe wrote many interesting songs, of which *Amo, Amas, I Love a Lass* became very popular.

Other Anglo-Irish dramatists of the late 18th century were: Charles Macklin (1697?-1797); Paul Hiffernan (1719-1777), Francis Gentleman (1728-1784), Isaac Bickerstaffe (1735-1812), Robert Jephson (1736-1803), Frederick Pilon (1750-1788), Leonard MacNally (1752-1820), infamous in Irish history as an informer, William Preston (1753-1807), Walley Chamberlaine Oulton (1770-1820), Isaac Jackman (fl. 1777), William Macready (fl. 1780), and Andrew Franklin (fl. 1785).

Irish Dramatists of the 18th Century.—In the 19th century, Irish writers still dominated English dramatic literature. This is not to claim for them that they were great dramatists for, as is well known, the English drama degenerated in that century. Dion Bouicault (1820-1890) was a prominent writer of melodramas. He had a sentimental love of Ireland but, being Anglo-Irish, he was not completely aware of the Gaelic tradition. Consequently the characters in his plays are little better than the stage Irishmen of older plays—slightly better dressed and less wild. Yet, despite his obvious weakness as a playwright, he was superior to most of his contemporaries. His faults were those of his generation—a love of splendor and of melodrama. *The Colleen Bawn* is still remembered and frequently produced. Bouicault spent some time in the United States, and his play, *The Octoroon* (1859), exhibits a picture of life in the southern United States.

James Kenney (1780-1849) was also a prolific playwright, for he wrote upward of 50 plays. He was so popular that Byron, in his *English*

Bards and Scotch Reviewers, makes a slighting attack on him:

Yet what avails their vain attempts to please,
While British critics suffer scenes like these; . . .
While Kenney's "World"—ah, where is Kenney's wit?—
Tires the sad gallery, lulls the listless pit.

James Sheridan Knowles (1784-1862) was considered by some of the best critics to be "the first tragic writer of the age." While that is an overstatement, it may be true to say that he was the author of the best acting plays of the period. *Virginius* is considered his best play—and the character of Virginius was William Charles Macready's most popular portrayal.

Other Anglo-Irish dramatists of the 19th century were: Andrew Cherry (1762-1812), John Till Allingham (fl. 1799-1810), Samuel Lover (1799-1868), Joseph Stirling Coyne (1803-1838), and George Francis Armstrong (1845-1906).

Oscar Wilde (1856-1900) is one of the best known of all the Anglo-Irish playwrights. Although he lived at a period when a new romantic movement in Anglo-Irish literature was being formed, his plays belong to the 18th-century tradition. His mother was nationalistic and had given her son two very Irish middle names, Fingal O'Flahertie, but he ignored Ireland and wrote entirely for a wider public. Wilde's plays belong to the "manners" tradition, and all the characters portrayed by him are taken from upper-class English life. He moved in that society and wrote only about the life which he knew intimately. His best-known play is *The Importance of Being Earnest*. Wilde's weakness as a dramatist, according to William Archer, is that "he treated the art of the dramatist with contemptuous insincerity." He was so in love with style that he put up more than his subject matter could carry. But, for all that, Wilde was a fine dramatist and, as Frank Harris predicted, "he will live with Congreve and Sheridan as the wittiest and most humorous of all our playwrights." If any Irish influence is to be found, it must be sought in the subtle psyche which hovers between the lines, but his contribution to English dramatic literature is no less because of that. Oscar Wilde's plays were the final flowering of the old tradition, for after Wilde's death another Anglo-Irishman, W. B. Yeats (1865-1939), gave English drama a new turn and a new inspiration (see also IRISH LITERARY REVIVAL).

PROSE

To give an idea of the Irish contribution to English prose, one conveniently, if quite arbitrarily, may divide the writers into five general classifications: (1) those who went to live permanently in England, either through economic necessity or because they believed that their roots were there; (2) those who interpreted and explained Ireland to a foreign audience; (3) those who pictured Ireland as a savage and turbulent country and those who added a journalistic touch; (4) those who wrote popular "thrillers"; (5) those who wrote about Ireland out of their own experience.

Authors Domiciled in England.—The only link with Ireland of the writers in the first category lies in the fact that their Irish temperament showed through their work, even though they made no attempt to portray Irish life. To this category belong Jonathan Swift, Richard Steele, Laurence Sterne, Oliver Goldsmith, and many

others. Swift was the greatest of them all. He was the dean of St. Patrick's (Protestant) Cathedral, Dublin. Swift wrote, not for an Irish or an English public, but for himself and for humanity. He was not bound by a narrow nationalism when he wrote his *Drapier's Letters* demanding justice for Ireland; he was fighting for a principle and not for a nation. Every nation may claim Swift, just as all may claim Shakespeare. As H. L. Mencken has shown, Swift had the true universal approach—he began by attacking the Irish as a race of Yahoos, then proceeded to assail the English, and ended by condemning the whole human race. As if to make his judgment on humanity emphatic, he ended his own life in a blaze of insanity. He hated ignorance and stupidity, and he lashed that which he detested with a savage satire. This is certainly one facet of the Irish character.

Swift, no doubt, would ridicule any claim that he was an Irish writer, but he would deny even more indignantly that he was an English one. He had a rebellious and intellectual mind, which diverted Anglo-Irish writers from that sentimental approach to Ireland which damned a considerable portion of 19th-century Irish literature. The liberal attitude, bordering on revolution, of such Anglo-Irish writers as Henry Grattan (1746-1820) and Edmund Burke (1729-1797) must be attributed in a great measure to Swift's influence. If Swift had a contempt for the Yahoos in Ireland, he had also an equal contempt for the Yahoos in every other country. He made Anglo-Irish writers conscious of their individuality, and established for them a tradition which, if not Irish, was just as certainly not English. It is for this reason that he frequently is called the father of Anglo-Irish writing.

Richard Steele, already mentioned as a dramatist, also belongs to this classification, although his sentimentality occasionally compels him to acknowledge his Irish lineage. Steele is recognized with Addison as the writer who did most to establish the essay as a special literary form. *The Tatler*, founded by him in 1709, was the precursor of the modern newspaper. Yet, despite his sentimentality, he must have inherited much of the rebelliousness which is so much a part of Swift. In 1710 he lost his government position because of a satire which he had written, and later he was expelled from Parliament on the charge of seditious libel.

Laurence Sterne left Ireland in his boyhood for England, and later indulged in European travel for his health. Many regard his *Sentimental Journey* (1768) and his novel *Tristram Shandy* (1760) as obscene. *Tristram Shandy* was denounced by Dr. Johnson, Oliver Goldsmith, Horace Walpole, and others, on moral and literary grounds. Some claim that Sterne represents a definite facet of Irish character, though most Irishmen would deny it.

Oliver Goldsmith is easy to recognize as an Irishman, if only because of his casual attitude to life. It is said that he was so sentimentally charitable that he often gave away money which he himself badly needed. Goldsmith has been described as "an inspired idiot," but unjustly so. His foolishness was assumed to guard his integrity—a very Irish trait. Goldsmith's contribution to the development of the essay is considerable, and his *The Vicar of Wakefield* (1766) is a polished novel, though it was written long before the novel-form was completely developed. His

writing has charm, a quality which some ascribe wholly to his racial heritage. Goldsmith achieved greatness.

Other creative writers of prose belonging to this classification were: Roger Boyle (1621-1679), who wrote a long romance entitled *Parthenissa*, Richard Head (1637-1686), Mary Davys (fl. 1756), Henry Brooke (1703-1783), Richard Griffith (d. 1788), William Chaigneau (1709-1781), Charles Johnstone (1719-1800), Frances Sheridan (1724-1766), Elizabeth Ryves (1750-1797), James White (d. 1799), John Corry (fl. 1825), Adelaide O'Keeffe (1776-1855), Thomas Moore (1779-1852), Lady Morgan (1783-1859), James Sheridan Knowles (1784-1862), the Countess of Blessington (1789-1849), and Elizabeth Hardy (1794-1854).

Interpreters of Ireland to Others.—To the second classification (those writers who attempted to explain Ireland to foreigners) belong Maria Edgeworth (1767-1849), Charles Lever (1806-1872), Samuel Lover (1797-1868), William Hamilton Maxwell (1792-1850), and some others. Maria Edgeworth was by far the best writer of this group, but this distinction does not mean that she was a writer of the first importance. She was, indeed, a minor writer, because her range of vision was narrow and because her knowledge of the common people of Ireland was derived merely from casual observation of the peasants on her father's estate. She wrote about Ireland as truthfully as she knew how, and her novels at least give a good picture of the "Big House" and all that it entailed in Ireland. In literature, *Castle Rackrent* (1800) marks the first appearance of an Irish peasantry drawn truthfully instead of their customary misrepresentation as uncouth creatures suffering from semilunacy. Edgeworth portrayed the life of the Irish governing classes and of the rising middle class.

Charles Lever, in dedicating his novel, *Jack Hinton the Guardsman*, stated: "I have no presumptuous expectation of elucidating the mysteries or of solving the difficulties of Irish character, but with the less ambitious object of exhibiting some of their peculiar features, some of their moods of mirth and melancholy, I have ventured in these sketches." Actually Lever elucidated only his own incompetence as a novelist of Irish or any other life. His intention was probably good, but his achievement was meager. In *Harry Lorrequer*, and in his other novels, he catches nothing of the real Irish spirit, and succeeds only in portraying the stage Irishman of older days. Lever's novels are now forgotten, but for a time Lever was the most popular novelist of his day. He is interesting now only as a phenomenon representing the misguided attitude of the less intelligent Anglo-Irish toward their country.

Samuel Lover, though his intention was the same as Lever's, achieved more because of his poetic mind. His best-known novel, *Handy Andy* (1824), is, of course, stage Irish, but the opening chapter is so funny (in a farcical way) that it almost lifts it above mediocrity. The character represented by Handy Andy is an Irish peasant who is constantly making idiotic blunders. The novel was so popular that the word Handy Andy has found its way into the dictionaries.

Depicters of a Tumultuous Ireland.—The writers placed in the third category (those who pictured Ireland as a savage, turbulent country) differ from those in the second class only in de-

gree. The mood in the novels of Maria Edgeworth and Charles Lever was calm. The Irish peasant may have been a blundering idiot, but he was not dangerous. In the novels of the Banims and of Gerald Griffin, however, he is pictured as a savage person with turbulent passions. John Banim (1798-1842) has been described as the Walter Scott of Ireland, because he wished to do for Ireland what the Waverley novels had done for the Scottish people. So in 1823, with the collaboration of his brother Michael (1796-1874), he began the project of *Tales of the O'Hara Family*. The first series of stories was very popular, and further series were issued until the death of John, whose portrayal of the Irish peasant was utterly false and lacked humor. Although Michael Banim wrote the best story of the series, *Crohoore of the Billhook*, he did not write any more after his brother's death.

The novels of Gerald Griffin (1803-1840) were of the same type as those of the Banim brothers, and of no higher quality. In 1828 appeared his *Tales of the Munster Festivals*, written while he stayed with his brother in Kerry. They were so well received that Griffin began a full-length novel, *The Collegians*, which he finished (1829) in London. The Irish revolutionaries of 1848 accepted *The Collegians* as an outstanding novel of Irish life. This is no tribute to their literary judgment, because the novel is melodramatic and false, not only to Irish life but even to nature. The misfortune of Griffin was that he thought that he was writing seriously of Ireland, when he peopled his novel with villains of the deepest dye and heroes of the highest integrity. If *The Collegians* is read today, it is because of its comic appeal. Dion Boucicault turned the story into a highly successful melodrama, *The Colleen Bawn*.

Other Anglo-Irish writers who fit into this category (however awkwardly) were: Sir Martin Archer Shee (1769-1850), Edward Mangin (1772-1852), George Croly (1780-1860), Robert Bell (1800-1867), Miles Gerald Keon (1821-1875), and Kathleen O'Meara (1839-1888).

Writers of Emotional Fiction.—In the fourth classification (those who wrote "thrillers"), Charles Robert Maturin (1782-1824) and Joseph Sheridan Le Fanu (1814-1873) are the most important. While the novels of Maturin, who wrote of the supernatural, had little merit in themselves, they had a great influence on the rising romantic school of France; and even on Sir Walter Scott, who not only reviewed and praised *Montorio* but also imitated *The Milesian Chief* in his own *The Bride of Lammermoor*.

Le Fanu was Ireland's best writer of "thrillers." While other writers in this medium were content to place the scene of their stories in lands where the impossible might be accepted as probable, Le Fanu was more precise and gave definite time, place, and environment to his subject. Le Fanu's stories are highly melodramatic, eerie in the extreme, and reminiscent of the stories of Edgar Allan Poe. They are still very readable. His best novels are *Uncle Silas* and *In a Glass Darkly*.

Other Anglo-Irish writers who may be mentioned here were: Regina M. Roche (1764-1845); Harriet L. Martin (1809-1891); Lady Lytton (1802-1882), author of *Cheveley*, or *The Man of Honour* (1839), a novel in which she made her husband the villain; Marmion W. Savage (1803-1872); Mayne Reid (1818-1883); (Bartholomew)

Elliot Warburton (1810-1852); and Sir George Tomkyns Chesney (1830-1895).

Delineators from Personal Knowledge.—William Carleton (1794-1869) is not only the best writer within the fifth classification (writers about Ireland as they knew it), but possibly the best Irish novelist. Carleton was a Gaelic-speaking peasant and therefore not properly an Anglo-Irishman. No one before or since his time has written so faithfully, so simply, so powerfully, and so well of the Irish peasant. Carleton was born in Ulster, the most historic part of Ireland. He was conscious of Ireland's tradition for the simple reason that he was conscious of himself. He did not write romantically of the country, because poverty at home made him aware of Ireland as it really was. Moreover, he wrote in an authentic Irish idiom, of which the dialogue in the plays of the Irish literary renaissance is only a pale shadow. Carleton's *Traits and Stories of the Irish Peasantry* are brilliantly realistic and are a better picture of the Ireland before the Famine (1845-1850) than anything which may be read in a history book. One of his most admirable characteristics is that he never shrinks before emotion, while at the same time he avoids sentimentality. Probably Carleton's best story is *Dennis O'Shaughnessy Goes to Maynooth*. He wrote many novels, but these are of less interest than his short stories. He turned Protestant that he might receive the patronage of the wealthy, but despite this fact he represented Catholic Ireland more accurately than any other writer. Carleton's stories are not popular, because they are written in a difficult dialect of English.

Other writers who attempted to write about Ireland sympathetically were: Anna M. Hall (1800-1881), Charles J. Kickham (1826-1882), Emily Lawless (1845-1913). None of them, however, rose above the mediocre.

The writers for *The Nation* newspaper, founded in 1842 by Thomas Osborne Davis (1814-1845) and Charles Gavan Duffy (1816-1903), are worthy of mention. Here was the first deliberate attempt to found a school of Irish literature in the English language. Most of the writers for *The Nation* were Anglo-Irish Protestants; and all were extremists who believed in revolution and who rejected, as un-Irish, literature which did not obviously breathe the Irish spirit. The greatest of the writers belonging to this group was John Mitchel (1815-1875). He was, of course, a revolutionary, was transported to Australia as a felon, escaped to the United States, fought for the South in the American Civil War, and edited (1864-1865) the *New York Daily News*. Mitchel's *Jail Journal* is the bible of revolutionary Ireland. It describes his travels to Van Diemen's Land (Tasmania), and its theme is that only through revolution can there be hope of freedom. There are some fine descriptive passages in the book, which is still fresh, even though the ideals for which he fought have largely been achieved.

Thomas D'Arcy Magee (1825-1868) merits mention here for his *History of Ireland*, which often is more creative than factual. He escaped from Ireland in 1848 and became editor for a time of the *Boston Pilot* which was edited later by another escaped rebel, John Boyle O'Reilly (1844-1890).

Lady Wilde (1826-1896) contributed under the name "Speranza" to *The Nation*; she was

very nationalistic, and wrote *Ancient Cures, Charms, and Usages of Ireland* (1890) and similar works. She was the mother of Oscar Wilde (q.v.), who, it must not be forgotten, was a brilliant writer of prose. He wrote some delightful fairy tales but is best known as a prose writer for *The Picture of Dorian Gray* (1891).

Irish writers also contributed extensively to English literature as historians, philosophers, orators, scholars, and journalists. (For Irish prose writers after 1900, see IRISH LITERARY REVIVAL.)

POETRY

Almost every writer thus far mentioned wrote also in verse. Swift was a not inconsiderable poet, as his *Stella's Birthday* and other poems adequately demonstrate. Goldsmith is well known as a poet of importance, and his *The Traveller* and *The Deserted Village* have a permanent place in English poetry. Richard Brinsley Sheridan wrote some pleasant songs, which may be found scattered throughout his plays. John O'Keefe, another playwright, wrote some romantic songs, which are not entirely forgotten.

Nahum Tate (1652-1715) and Nicholas Brady (1659-1726) published in 1696 their joint metrical *New Version of the Psalms of David*. Tate, though elected to the position of poet laureate, added little to the glory of Irish literature, for he was regarded by Pope and other writers of authority as possibly the worst poet who ever held that position.

19th-Century Poets.—It was not until the 19th century, however, that Irish poets, becoming conscious of Ireland and her tradition, wrote best. In Ireland, 1798 was a year of revolution, when many Anglo-Irishmen associated themselves definitely on the Irish side against Britain. As has been shown, they knew little of Gaelic-speaking Ireland until then, but the spirit of nationalism was abroad, and they quickly sensed the importance of uniting themselves completely with every facet of Irish life. First came Charlotte Brooks (1750-1803) with her series of translations, *The Reliques of Irish Poetry* (1789). Then followed Jeremiah Joseph Callanan (1795-1829) and Edward Walsh (1805-1850), who in their translations from the Gaelic reproduced faithfully the wavering rhythm of the Gaelic verse-form. Callanan's best known translation, *The Outlaw of Lough Lene*, begins:

Oh, many a day I have made good ale in the glen,
That came not of steam or malt—like the brewing of men.
My bed was the ground; my roof, the greenwood above,
And the wealth that I sought, one far kind glance from
my love.

But the real link between the Anglo-Irish and Gaelic-speaking Ireland was through music, and it was provided by the *Irish Melodies*, composed between 1807 and 1834 by Thomas Moore (1779-1852). For a century Moore was regarded as Ireland's national poet, but it must be admitted that his reputation was based partly on his brilliance in the world of society. His songs were just sufficiently Irish in a polite way to make them attractive to an English audience. For this reason his influence in England was great and, without question, he contributed much to establish the idea in the English mind that the Irish were not a race of barbarians. More important still, he gave courage and inspiration to Irish writers. Moore's verse is essentially too superficial and facile to have been a major influence, but it was just the thing at that time to

establish the idea of a dignified Ireland with long traditions. Moore knew little of Ireland's history, but he was captivated by the Irish melodies of the 17th and 18th centuries, and he succeeded in putting appropriate words to them which, in a peculiar way, expressed something of Ireland's national spirit and aspiration. He came closest to the true poetic spirit in his *Avenging and Bright* and *At the Mid Hour of Night*. Occasionally he achieved the Gaelic cadence. Moore's weakness is derived from the fact that he was not sufficiently close to the source of Gaelic inspiration.

Verse in "The Nation."—*The Nation*, and the spirit of violent nationalism which it propagated, brought into existence a whole school of verse writers. Men with a talent for writing verses, and many others who had none at all, thought it their duty to express their nationalistic emotions and political ideas in verse. The result of this was that much of the verse of the *Nation* school is too didactic and rhetorical to warrant its classification as poetry. Thomas Osborne Davis (1814-1845) is the best representative of this group. His *My Land* is probably his best piece, but *A Nation Once Again* was his most popular song, and for a long time it was accepted as Ireland's unofficial national anthem. John Kells Ingram (1823-1907), a professor in Trinity College, contributed a rousing song—*Who Fears to Speak of Ninety-Eight?*—to *The Nation*. It was so great a success as a battle cry that the author's conscience disturbed him and he later disclaimed authorship. Another good song writer was John Keegan Casey (1846-1870), who is best remembered for his rebel song, *The Rising of the Moon*. Ireland's greatest ballad, *The Wearing of the Green*, and that other stirring song, *The Shan van Vocht*, belong to an earlier period; no one knows who wrote them. Two other famous Irish ballads, *The Croppy Boy* and *Johnny, I Hardly Knew Ye*, are also anonymous.

James Clarence Mangan (1803-1849), Ireland's most intense poet, also contributed to *The Nation*. However, it cannot be said that he properly belonged to that school of writers. Mangan was a distressed spirit and not a propagandist. His free translations from Gaelic are among the best poems written by Irishmen in English. His *O'Hussey's Ode to the Maguire* has great power, and his *Dark Rosaleen* and *The Woman of Three Cows* are far superior to their Gaelic originals. Probably his best original poem is *The Nameless One*. It is autobiographical and full of passion:

Roll forth, my song, like the rushing river,
That sweeps along to the mighty sea;
God will inspire me while I deliver
My soul to thee! . . .

Go on to tell how, with genius wasted,
Betrayed in friendship, befooled in love,
With spirit shipwrecked, and young hopes blasted,
He still, still strove. . . .

There is little doubt that Mangan was Ireland's greatest poet. Students of Mangan should not miss reading John Mitchel's excellent essay on him, which is included in an edition of Mangan's collected poems.

As translators from Gaelic, Sir Samuel Ferguson (1810-1886), for his *Cashel of Munster*, and Thomas William Rolleston (1857-1920), for his *Clonmacnoise*, should be mentioned. Other Irish poets of some account are: William Dren-

nan (1754–1820), Richard A. Millikin (1767–1815), Charles Wolfe (1791–1823), William Carleton (1794–1869), Samuel Lover (1797–1868), Aubrey Thomas de Vere (1814–1902), William Allingham (1824–1889), Timothy Daniel Sullivan (1827–1914), John Todhunter (1839–1916), John Boyle O'Reilly (1844–1890), Emily Lawless (1845–1913), and Alfred Perceval Graves (1846–1931).

Oscar Wilde resembled Goldsmith in that he succeeded brilliantly in almost every form of literature. His *Hélas!* is a sonnet of great strength, and his *The Ballad of Reading Gaol*, written while he was in jail, holds a permanent place in English poetic literature.

(For the contribution of Irish poets to English literature after 1900 see IRISH LITERARY REVIVAL.)

IRISH MUSIC. From references in early medieval manuscripts it is clear that music played an important role in the life of the ancient Irish. Music-making is mentioned in connection with banquets and ceremonious occasions, warfare, and the casting of spells; and harpers figure in many of the legends. The chief instruments in use in the earliest period were the five- or six-stringed quadrangular harp (as represented on the stone cross at Castledermot, County Kildare), the *tympan* and the *fidil* (stringed instruments played with a bow), and the *piopai* (bagpipe), which was the instrument of the humble folk. Military instruments were the *corn* (horn) and *stoc* and *sturgan* (two types of trumpet). The triangular harp, of which representations are found from the 11th century on, seems to have been introduced into Ireland by the Norse invaders. In its Irish form it was not strung with hide or horsehair but with metal—iron, silver, or bronze; it ranged in size from the small *ocht-tedach* (an eight-stringed instrument used to accompany singing and hung from the girdle) to the larger and more resonant *clairseach*, of which the earliest example extant is the so-called Brian Boru harp (having 30 strings and dating from about the 13th century), which is now in the library of Trinity College, Dublin.

Church Music.—Some evidence exists to show that the ecclesiastical chant was brought to Ireland in the 5th century by St. Patrick himself; but, contrary to the general belief, the chant sung in Ireland was not Roman but Gallican—as practised in Gaul up to the 8th century. Roman chant does not seem to have been introduced into Ireland until the period of the Norman invasion—with the advent of English and continental orders. Though great schools of learning flourished in Ireland from the 6th to the 10th century, and Irish monks were active missionaries all over western Europe, there is little evidence to

support the assertions made by Grattan Flood and others concerning their contributions to the development of western church music; the term "Irish Anglo-Saxon" neume-type, coined by no less an authority than Peter Wagner, is fanciful as far as the Irish element in this neume-type is concerned. The earliest known instance of music notation in an Irish manuscript occurs in the 11th-century Drummond Missal, in which the chant of parts of the mass is indicated by means of neumes—characters of a notation which is the progenitor of our present-day system of music notation. But the Drummond Missal is a Roman missal adapted to local uses, and none of the chants mentioned so frequently in medieval Irish literature have so far come to light.

Whereas, on the Continent, polyphonic music gradually evolved during the early medieval period in the monasteries and churches, in Ireland, the Norman conquest, the clash between the native traditions and those of the invaders, and above all the wars, plantations, and persecutions of the succeeding centuries, combined to deny to church music a normal course of development. The surviving musico-liturgical manuscripts embody a tradition derived from the English, Anglo-Norman, or Continental houses which became established in Ireland from the 12th century.

Harp Music.—Throughout the medieval period, however, the native tradition of music, especially of harp-playing, continued to flourish. Writers such as Giraldus Cambrensis in the 12th century, Dante in the 13th, and Galileo in the 16th pay tribute to the excellence of Irish harp-playing, and numerous masters of the instrument are mentioned in the annals. At the courts of the princes and chieftains, poems composed by the *file* or *bard* were recited or chanted by a *reacaire*, to the accompaniment of an *oirfeadach* (harper). The professional harper ranked, according to the Brehon Laws, as a *bo-aire* (non-noble rent-paying freeman with property), and was the only musician entitled to "honor price"—an additional fine payable by reason of his rank in the event of injury.

Unfortunately we have little information as to the nature of the music played by the harpers. The long panegyric poems recited or sung in the halls of the nobility were so complex in meter that they could not have lent themselves to a musical setting in our sense of the word. It is possible that the main part of the verse was chanted in a monotone, punctuated with cadential melodic inflections in the manner of psalmody, and supported by chords on the harp. Such a method of performance is described as surviving in Mayo as late as the 18th century. As regards the harp music itself, a 17th-century Welsh manuscript in the British Museum (Add. MS. 14905), transcribed from an earlier manuscript and purporting to contain early medieval Welsh harp music, may give some inkling as to its style, since the Welsh and Irish traditions of harp-playing were closely related. Arnold Dolmetsch has deciphered the tablature in which the manuscript is written, and parts of the transcription have been performed and recorded, revealing a style quite unlike that of any music hitherto known; primarily harmonic in its texture, it embraces curious chord-formations and conveys a remote, other-worldly atmosphere by means of methods which seem decidedly impressionistic. However, many aspects of this manuscript are still problematical, and our factual knowledge of

Irish harp-playing is limited to some technical points. The wires, plucked by the harper's long, crooked nails, produced a sweet and tinkling tone very different from the more robust tone produced by gut strings. Owing to the excessive vibration, each string had to be damped before the next was plucked, involving a technique so exacting in the case of fast-moving passages that unless the player started at an early age there was little hope of his becoming proficient. Chords were played downwards, not upwards as today, and there seems to have been much doubling of the melodic line in octaves. In general, the style of playing was fluent, delicate, and highly-ornamented.

Decline of the Harp.—Throughout the wars of the 14th and 15th centuries, and the plantations of the 16th century, the harpers continued to practice their art; and though penal enactments against harpers and rhymers were made intermittently for over three centuries—from the passing of the Statute of Kilkenny in 1367 to the reign of William of Orange—such measures (savagely carried out) were primarily directed against the strolling entertainers, who were often politically active, and not against the harpers patronized by the nobility. After the Battle of Kinsale (1601), however, with the final passing of the old Gaelic order, harp-playing began to decline. The families which had patronized the harpers were for the most part outlawed and their estates confiscated, the planters who immediately succeeded them were no supporters of native art, and harp-playing, from being a privileged calling, fell to being a humble one. In the heyday of medieval minstrelsy, poet, singer or declaimer, and harper were three specialists who combined in the performance of poetry, but now these offices were merged in the one individual. At the same time the esoteric bardic poetry and harp music, unintelligible to the *nouveau riche* as to the simpler folk to whom the harpers had now to turn for support, gave way to popular verse and tuneful music in the folk style. Such music had, of course, coexisted with the earlier bardic art, but from now on it was to become the main vehicle of expression.

Carolan.—With the comparative tranquillity which followed the Treaty of Limerick (1691), conditions became more favorable for the pursuit of music, and the rural gentry, including the few native families who had not been dispossessed, began to cultivate European as well as native music. During this period lived the last and greatest of the poet-harpers, Turlough Carolan (1670-1738), who composed many hundreds of songs, chiefly in honor of his patrons, both Irish and Anglo-Irish, whose houses he visited in the course of his travels. The songs, named after the patrons to whom they were addressed, were sung by the blind poet-composer to an accompaniment on his harp. Gay, humorous, or elegiac, they show great versatility, some being in the traditional style and based on gapped scale-forms, others clearly revealing the influence of contemporary Italian music—such as Carolan would have heard in the drawing-rooms of his patrons. An edition of some of Carolan's songs was published in Dublin by John and William Neale about 1720—the earliest surviving example of music printing in Ireland.¹

¹ A monumental work on Carolan by Donal O'Sullivan, *Carolan, his Life and Times*, including an edition of some 200 of his songs, remains unpublished for lack of funds.

The harpers who succeeded Carolan were ex-cultants only; they continued to dwindle in numbers, and were mostly in straitened circumstances. If changed social conditions were responsible for the fate of the harpers, the decline of the harp itself, which had been so popular an instrument for amateur music-making in the previous century, is explained by the difficulty of its technique as compared with that of keyboard instruments; as well as by the fact that, being a diatonic instrument, it could not cope with the ever-widening range of modulation and of chromaticism during this period—such as was readily available on the harpsichord, the violin, and (when it appeared towards the latter part of the 18th century) the piano.

Belfast Harp Festival.—Before the last vestiges of the harp tradition had died away, an attempt was made to preserve them by the organization of harp festivals—at Granard from 1781 to 1785, and at Belfast in 1792. At the latter festival Edward Bunting, a Belfast organist, noted down the tunes played by the harpers, and these notes were later drawn on for his three-volume *Ancient Music of Ireland*, the first important collection of traditional music. Unfortunately Bunting's method of notation was a primitive one. In the case of songs, since he knew no Irish, the words were not noted with the tune. In the case of harpers' airs, no distinction was drawn between what was sung and what was played, and the reproductions of traditional harp music in his 1840 volume consist almost entirely of elaborate piano arrangements constructed out of purely melodic jottings made many years earlier. Despite its shortcomings, however, Bunting's collection was a notable work for its time, and has remained the chief source of what little information we possess with regard to harp-playing in Ireland.

Folk Song Tradition.—At the end of the 18th century the tradition of folk song was still fully alive throughout the country. Countless airs were in circulation and new poems continually written for the more well-known airs. While Irish remained the language of the vast majority of the people this tradition was able to hold its own, even against the rise of the English ballad—for popular English songs such as those of Charles Dibdin (q.v.) began to have a vogue in Ireland at the turn of the century. But with the suppression of the Irish language in the schools and its gradual abandonment as the vernacular in the second half of the 19th century, the tradition of folk song commenced to suffer the fate which had already befallen the harp music.

Moore's "Melodies."—From 1808 to 1834 the *Irish Melodies* of Thomas Moore (q.v.) appeared serially in ten volumes—melodies from the Bunting and Holden collections to which the poet wedded his admirable lyrics. The *Melodies* achieved an immense popularity, and were instrumental in making Irish songs known to the townsfolk, to whom traditional singing was a closed book, and known in England and abroad. Were it not for Moore's *Melodies*, on the general abandonment of the Irish language the majority of the people would have lost all touch with their own music. But the *Melodies*, elegant, nostalgic, and sentimental, were far removed from the elemental beauty of traditional singing in Irish, which continued to decline in all but the remoter districts.

Folk Song Collections.—Fortunately, a number of collectors throughout the 19th century

worked to place on record what remained of this rich store of song, chief among them William Forde, and John Edward Pigot (whose collections have remained for the most part in manuscript), George Petrie, and Patrick Weston Joyce. The transcription of folk song, however, particularly of that free, unmeasured style so usual with Irish traditional singers, can only be partially successful; for such limited methods of notation as the rank and file of collectors use are inadequate to reproduce the irregular meter, the subtle rhythmic nuances, and the peculiarities of intonation due to the survival of other scale-forms, which are so essential a part of the tradition. The early collectors were too often ignorant of the mode-systems underlying the airs, so that foreign key-signatures and accidentals, and even changes adopted to make the airs "conformable to the laws of harmony" have to a certain extent become incorporated in the corpus of traditional music as taken down in the collections. Careful and scholarly methods, such as those adopted by Martin Freeman in his Ballyvourney Collection (*Journal of the Irish Folk Song Society*, vol. 6), were rarely in evidence. The ideal method of preserving folk song is, of course, by means of recording plus transcription, and this method has been adopted by the Irish Folklore Commission, which houses among its collection of some 3,000 folk songs a large number of ediphone recordings.

Taken all in all, the preserved corpus of Irish folk music is generally believed to be the finest and most varied produced by any nation. Song airs—plaintive, lilting, rugged, or wild and sweeping—shapely narrative airs, religious songs, lullabies, occupation songs, drinking and martial songs, are all to be found, showing the widest range of tonality and the simplest, symmetrical structures as well as chain-structures of the most intricate kind. Incredible as it may seem, there is no specific reference to dancing in early Irish literature, and the dance music—reels, jigs, horn-pipes and "set" dances—is of relatively modern origin.

Clash of Traditions—Anglo-Irish Music.—Irish folk music, unlike that of nations whose music followed a normal course of development, has never been properly assimilated into a broader tradition of art music, due to the chasm—political, social, and religious—which existed for centuries between the spontaneous song in the vernacular which was the natural expression of the Irish people, and the purely English tradition of music-making in the towns.

Ever since the Norman invasion a musical culture had begun to develop in the Pale (the English settlement around Dublin), and other centers of English or Anglo-Norman influence, which had few points of contact with the music of the native Irish. Most of the records are ecclesiastical, and manuscripts such as the 14th-century psalter of Christ Church show the Anglo-Norman tradition of Christ Church and St. Patrick's Cathedrals in Dublin. There seems to have been little creative activity, however, and certainly no counterpart to the school of polyphony which flourished in England from the 15th to the 17th centuries.

Secular music in the towns also seems to have followed an English pattern. It is significant that six of the *Cantilenae* for festivals and other occasions written in the 14th century by Richard Ledrede, bishop of Ossory, for the use

of the vicars choral of Kilkenny Cathedral were directed to be sung to English tunes, and two to French tunes. In Kilkenny, as elsewhere, ordinances were issued forbidding Englishmen to speak Irish, and the music as well as the language of the "wilde Irishrie" would have fallen equally under the ban.

The vicissitudes of Anglo-Irish church music may be understood, in face of the wars of the 14th century, the lax and confused state of religious organization in the 15th, and the wholesale confiscation of monasteries in the 16th. Superimposed on the old conflict between native and foreign religious establishments was now the new conflict which arose with the Reformation. After the Reformation English organists and vicars choral were frequently imported, and two noted madrigal writers of the English school were appointed organists at Christ Church Cathedral, Dublin—John Fermer, who held this post from 1596 to 1599, and Thomas Bateson, who held it from 1608 to his death in 1630. During the Cromwellian period church music was suppressed and organs removed or destroyed, and in some of the cathedrals the services were reduced to those of a mere parish church.

Music in Dublin.—Towards the end of the 17th century, after the turmoil of the Jacobite wars had subsided, conditions became more stable, and Anglo-Irish music entered on a period of prosperity which was to lead to Dublin becoming one of the most musically active cities in Europe. A large number of musical societies came into being, among them the Hibernian Catch Club (the oldest body of its kind still in existence), while concerts for charitable purposes, "benefit" concerts, and performances of ballad opera became the vogue. Crow Street Music Hall was built by the Dublin Academy of Music in 1730 "for the practice of Italian music," and the New Musick Hall, in Fishamble Street, was opened in October 1741. Here George Frederick Handel gave the first of his series of Dublin concerts on December 23 of the same year, and on April 8, 1742, he gave the first public performance of the *Messiah*, amid unprecedented scenes of enthusiasm. Handel's visit was followed by that of Thomas Augustine Arne, who between 1742 and 1744 produced his masque *Comus* and his opera *Rosamund*, and gave the first performances of his oratorio *The Death of Abel* and his serenata *Masque of Alfred* at the Theatre Royal, in Smock Alley.

The eminent violinist Francesco Geminiani had been teaching in Dublin and giving concerts there from 1733 to 1740. His pupil, Matthew Dubourg, led the viceroy's band from 1728 to 1765, and had the privilege of assisting at the first performance of the *Messiah* and at Handel's other Dublin performances. In 1764 Garrett Colley Wellesley, 1st earl of Mornington (father of the duke of Wellington), a composer of church music and of glees, was appointed to the newly-created chair of music in Dublin University.

In the latter part of the 18th century Dublin could boast ten music shops (some of them firms of music publishers), eight harpsichord and piano manufacturers, three firms of instrument makers, and two firms of organ builders. Members of the Anglo-Irish aristocracy formed orchestras and cultivated chamber music, and the patronage of music as a social art was at its zenith. Creative activity was not lacking, the chief com-

posers being Lord Mornington and Philip Cogan.

19th-Century Music.—With the passing of the Act of Union in 1800 and the abolition of the Irish Parliament, Dublin lost most of its significance as a focal center of political and social life, and the patronage of music by the nobility began to wane. In the 18th century Dublin had not only been a hub of musical activity but had attracted eminent musicians from England and the Continent. In the 19th, the chief names to be recorded are those of Irishmen who lived and worked abroad, such as John Field (1782–1837), Dublin-born pianist and composer of nocturnes and piano concertos, who was the first Irishman to gain an international reputation as a composer; Michael William Balfe (1808–1870), also born in Dublin, composer of *The Bohemian Girl*; William Vincent Wallace (1813–1865), born in Waterford, composer of *Maritana* and *Lurline*; and a number of minor figures such as Thomas Simpson Cooke, William Rook, and George Alexander Osborne.

At the same time, a new consolidation of music in Dublin set in with the founding of a series of societies devoted to the regular performance of the orchestral and choral repertory. The earliest of these was the Sons of Handel, founded by Francis Robinson in 1810. This was followed by the Antient Concerts Society, founded by Joseph Robinson, son of Francis, which lasted from 1834 to 1863. At the International Exhibition, Dublin, of 1851 Joseph Robinson assembled a choir and orchestra of no less than 1,000 performers, while in 1856 another society, the Philharmonic, gave the first performance in Ireland of Beethoven's *Choral Symphony*. Later, Joseph Robinson founded the Dublin Musical Society, which gave regular performances from 1876 to 1902 with a chorus and orchestra of about 350. Towards the end of the century the chief figures in the musical life of Dublin were Sir Robert Prescott Stewart (1825–1894), organist at St. Patrick's Cathedral and for a time at Christ Church, and professor of music at Dublin University, who was a prolific composer of organ and church music, and Michele Esposito (1855–1929), an Italian who was appointed professor of piano at the Royal Irish Academy of Music in 1882. Esposito founded the Dublin Orchestral Society, conducting its concerts from 1899 to 1914, and as conductor, composer, pianist, and teacher he dominated music in Dublin for nearly half a century.

In Belfast, the Philharmonic Society, founded in 1874, has been the main source of concert activity, and the society's chorus and orchestra (conducted by Sir Robert Stewart from 1877 to 1890, and from 1913 to 1950 by E. Godfrey Brown) has continued to give an unbroken series of subscription concerts, at some of which major works by composers such as Edward Elgar, Granville Bantock, John Ireland, and Ralph Vaughan Williams have been conducted by the composers themselves.

Stanford, Harty, Moeran.—Sir Robert Stewart's pupil, Charles Villiers Stanford (b. Dublin, 1852; d. London, 1924), and Esposito's pupil, Hamilton Harty (b. County Antrim, 1880; d. London, 1941), proved to be the two most eminent Irish musicians of their time, though both, like their fellow composers earlier in the century, left Ireland at an early age and took up residence in England. Both were knighted for their services to music. Stanford's large output and his work as teacher of a whole generation of English composers belong to the achievements of the Eng-

lish school, but in his editions of *Moore's Irish Melodies* and of the *Petrie Collection of Irish Music*, and in such works as the *Irish Symphony* and the five *Irish Rhapsodies*, he paid tribute to the folk song of his native country. Harty was one of the greatest conductors of his age. As a composer his work is distinguished more for its orchestral virtuosity than for its intrinsic worth, but his tone-poem *With the Wild Geese* and the *Irish Symphony* still survive in the repertoire.

The tradition of Stanford and Harty has to a certain extent been carried on in the work of Ernest John Moeran (1894–1950), a composer of Irish extraction, whose chief works, the *Symphony in G Minor* and the *Violin Concerto*, owe much to the inspiration of Irish folk song and of the landscape and sea coast of County Kerry, where both works were for the most part conceived and written.

Modern Developments.—Due chiefly to the country's checkered history, the general organization of music in Ireland is much behind that of other countries. After World War I the main advances were due to the development of broadcasting. Radio Eireann supports a symphony orchestra of 65 players which gives symphony concerts twice a week in the Phoenix Hall, Dublin, and the broadcasting programs, which are relayed by stations at Athlone, Dublin, and Cork, provide the main source of music for the Irish public. The British Broadcasting Corporation, Belfast, has been an important factor in the revival of music in Northern Ireland, though its symphony orchestra was disbanded on the outbreak of World War II. Apart from broadcasting, recitals by artists of international reputation are given weekly during the season by the Royal Dublin Society. New standards in opera have been achieved by the Dublin Grand Opera Society, which holds two seasons annually, and has brought the casts of the Paris Opera Comique and the Hamburg State Opera to Dublin. The chief music festivals are the Feis Ceoil, a general festival music, and the *Oireachtas*, a festival of Irish music and of the Irish language and literature, both founded in Dublin in 1897; they are the prototypes of the network of music festivals and *feiseanna* held annually throughout the country, particularly in Northern Ireland. Chairs of music exist in Dublin University, the National University of Ireland (at the university colleges in Dublin and Cork), and the Queen's University, Belfast. Dublin has four schools of music (two public and two private) and Cork has one, but Belfast is without any. Concert activity in Dublin is severely handicapped by the lack of a concert hall, but Belfast has its fine Ulster Hall, and Cork its City Assembly Hall. The large music section of the Library of Trinity College, Dublin (Dublin University) is rich in manuscripts, and there is a noteworthy collection of harps, bagpipes, and Dublin-made harpsichords and pianos in the National Museum of Ireland.

The chief names in the modern musical annals of Dublin have been those of Count John McCormack (1884–1945), celebrated tenor; Vincent O'Brien (d. 1946), organist of the Pro-Cathedral; Fritz Brase (d. 1940), founder of the Irish Army School of Music and (1927–1936) conductor of the Dublin Philharmonic Society; and John F. Larchet, professor of music at University College, Dublin. The foremost authority on Irish folk music is Donal O'Sullivan, director of Irish folk song studies at University College, Dublin. Mod-

ern Irish composers include Herbert Hughes (d. 1937), E. Norman Hay (d. 1943), and Carl Hardebeck (d. 1946), the pioneer of the Irish folk song revival; John F. Larchet, Frederick May, Arthur Duff, Brian Boydell, Eamonn O Gallchobhair and Eamonn O Frighil. Conductors include Michael Bowles, music director and conductor, Radio Eireann (1941-1948), and J. M. Doyle, conductor of the Dublin Grand Opera Society and director of the Irish Army School of Music.

IRISH SCHOOLS AND SCHOOLMEN OF THE MIDDLE AGES.

The Irish monastic schools, dating from the 5th century, were celebrated all over Europe; the lay schools, though playing an important part in spreading learning at home, were not so well known. These two classes of schools were quite distinct all through the literary history of Ireland, and, without interfering with one another, worked contemporaneously. By the 7th century Irish missionaries were scattered all over Europe, and for more than two centuries Ireland maintained her glorious position. Then, in the 9th century, came the invasions by the Northmen, who spread destruction among the Irish schools and monasteries. As Ireland was a group of petty kings, her recovery was quicker than might have been expected. Towards the close of the 11th century, according to St. Malachy and St. Bernard, the old Irish monastic and missionary spirit had become dimmed, chiefly by the Norse invasions. These two saints apparently agreed on the introduction of the reformed Benedictines into Ireland. The Irish postulants, sent to Clairvaux to be trained under the eye of St. Bernard, returned to Ireland as professed monks in 1142 and laid the foundation of Mellifont; within ten years Mellifont founded seven new abbeys. Before the Anglo-Norman invasion of 1170, there were 12 Cistercian monasteries in Ireland, five of which had been founded from England and Wales.

The Anglo-Norman invasion, with the political division of the country between the native Irish and the "adventurers," brought about a division among the new religious foundations into Irish and English houses. The Dominicans were the first of the friars who came to Ireland, and their first house was in Dublin (1224), the center of the Anglo-Norman government. Yet, they soon had Irish foundations—Athenry, founded by Myler Bermingham (1241); Cashel, founded by David McKelly, archbishop of Cashel (1245); and Carlingford, founded by Richard de Burgh (1305). The Franciscan Province was established in Ireland about 1231, but its early houses were established chiefly at the seaports, where English influence was strong. Within 15 years (before 1256) Irish houses stood at Cashel,

Nenagh, Limerick, Multifernan, and New Ross. Between 1285 and 1325 the cleavage between Irish and English houses (Franciscan and Dominican) went on apace, so that (1325) the Franciscans definitely divided their houses. Nenagh, County Tipperary, became the custodian of the Irish friars, with Athlone, Ennis, Clare-Galway, Galway, Armagh, Cavan, and Killeigh as their sister houses. English influence was gradually shrinking, and the Irish houses consequently were adding to their numbers.

Religious Schools and Writers.—These are so numerous that space can be provided for only the most important. One of the earliest writers was Congan, abbot of Cistercian Suir Abbey (about 1150), who wrote the *Acts of Malachy* (archbishop of Armagh), *Epistles to St. Bernard*, and the *Acts of St. Bernard*. It was by his persuasion that St. Bernard undertook to write the *Life of St. Malachy*. Marian O'Gorman, abbot of Knock Abbey, County Louth (1171), wrote the supplement of the famous *Martyrology of Aengus of Tallaght*. John Duns Scotus (13th-14th centuries), the "Subtle Doctor" and Franciscan, has had his life and works edited by Luke Wadding, the celebrated Irish Franciscan, in 12 volumes (1639). Experts, however, are not agreed about the country of his birth, Ireland, Scotland, or England, or even about the year of his birth or of his death. Of the writers of the Cistercian Order, we can mention only a few principal ones. Matthew O'Heney, of Holy Cross Abbey, County Tipperary, afterwards archbishop of Cashel (1192-1206) and papal legate (1194), wrote, among other works (since lost), a *Life of St. Cuthbert, Bishop of Lindisfarne*, and several *Epistles to Pope Celestine III*. Henry Crump, doctor of divinity and professor at Oxford (1390), belonged to the Abbey of Baltinglass, County Wicklow (1382), and was a prominent opponent of John Wycliffe (Wiclif), English religious reformer. Donchadh O'Daly, abbot of Boyle, County Roscommon (d. 1250), "was an eminent bard, and in the hymnal species, was superior to all the poets of his time." Felix O'Dullany, of Jerpoint Abbey, County Kilkenny, governed the diocese of Ossory, 1178-1202, endowed the abbey, and was buried in a tomb on the north side of the high altar—where many miracles are said to have been wrought. Maurice MacGibbon, abbot of the Cistercian monastery of Nenagh (Maigue), Limerick (founded in 1148 from Mellifont), was appointed archbishop of Cashel in 1567; he had a strenuous time in Elizabeth's reign, and escaped to Oporto, Portugal, where he died in 1578.

The 15th century saw an enormous production of Irish annals, chronicles, and philosophical and theological treatises. John of Ireland (c.1460), a Dominican friar, published a *Manipulus Florum*, a "Collection of the best flowers out of all the Sacred Writers, proper for all subjects." One Malachy O'Lachnain, a secular priest of Killa-loe, wrote an *Antiquum Missale* consisting of psalms, offices, and lives of saints, in Gothic character and illuminated (MS. in Trinity College, Dublin). In the 16th century the *Whole Philosophy of John Scotus* was published by Maurice O'Fihely, a Franciscan and archbishop of Tuam, who also published a *Dictionary to Holy Scriptures* (Venice 1603). A James Walsh, an Irishman who became a divinity student at Oxford, translated into English the writings on Ireland of the celebrated Giralduus Cambrensis (Giraldus or Gerald de Barri Cambrensis). Writers on

philosophy and commentators on St. Thomas's writings continued in the 16th century. The latest was Edmund Tanner, bishop of Cork (1574-1579), who was the author of *Dissertations on the Summa of St. Thomas*.

Annals.—These are the materials for a real history of Ireland. The principal ones now remaining in the Gaelic language are those of *Tighernach*, *Ulster*, *Loch Cé*, *Inisfallen*, *Boyle*, *Connacht*, *Donegal*, and the *Chronicon Scotorum*. Those of *Clonmacnois* are lost in the Gaelic version, but a translation into English is extant (1627). Besides these, we have in Latin those of *Multifernam*, *Grace*, and *Clyn*. *Tighernach* died in 1088, but his *Annals* have been continued down to 1407. His compilation is a remarkable instance of the great learning and devotion to scholarly pursuits of the Irish laymen of the 10th and 11th centuries, and affords evidence of a cultivation and diffusion of literature which, at so early a period, would do honor to the history of any country. Fragments of these *Annals* are in the Bodleian and Trinity College, Dublin, libraries; they were edited by Whitley Stokes (1830-1909) in the *Revue Celtique*, vol. 16. In order of time, the next compilation of ecclesiastical and general historical records, is that of *Inisfallen*, about the year 1215; the monastery in *Loch Lein* (Killarney) dates from the 6th century, so that the compilation may have been begun about the 10th century. These *Annals* were reproduced in facsimile from the original manuscript (Rawlinson B. 503, in the Bodleian Library, Oxford) by the Royal Irish Academy, Dublin, in 1933. The *Annals of Boyle*, part in Irish and part in Latin, begin with the Creation and reach down to 1253; the Cistercian monastery at Boyle was founded quite near the ancient Irish monastery. The *Annals of Ulster* gathered the abundant materials that had accumulated since *Tighernach's* time down to 1498, the date of the death of the compiler, *MacManus*; *W. M. Hennessy* edited in four volumes, Irish and English (1887-1901), the manuscripts in Trinity College, Dublin, the Bodleian Library, Oxford, and the British Museum. The *Annals of Loch Cé*, near Boyle, County Roscommon, are known as a continuation of the *Annals of Tighernach*; the manuscript in Trinity College, Dublin, was edited and translated by *W. M. Hennessy* (London 1871). The *Annals of Connacht* begin with the year 1224 and end in 1562, but the years 1394-1397 are missing; the only copies extant are in Trinity College, Dublin, and the Royal Irish Academy. They are probably a fragment of the *Annals of the O'Duigenans of Kilonan*, County Roscommon. Of the history of the *Chronicon Scotorum*, by the celebrated *Duald MacFirbis*, little is known; three copies are extant—one in Trinity College, Dublin, and two in the Royal Irish Academy. *MacFirbis* was the last of a long line of lay historians and chroniclers of Tireragh, County Sligo. The compilation, which includes the period between 375 and 1135 A.D. and is one of the most authentic collections, is from more ancient annals (ed., *W. M. Hennessy*, London 1866). The only known copy of the so-called *Annals of Clonmacnois* is an English translation of the year 1627, in the quaint style of the Elizabethan period. It seems to be a faithful rendering of the original Irish version, and comes down to the year 1408. It was translated into English in 1627 by *Conell Mageoghagan* (ed., *D. Murphy*, Dublin. 1896).

The *Annals of the Kingdom of Ireland by the*

Four Masters are the most important of all in point of interest and historical value. Michael O'Clery, the chief of the Four Masters, and inspirer of the great national literary work, was born near Ballyshannon, County Donegal, in 1580, of a family of hereditary scholars, lay and ecclesiastical; he probably was educated by the Franciscans there, and became a member of the order. In 1627 he visited the various Irish religious houses and other repositories of ancient Irish manuscripts and laboriously copied all the important tracts dealing with the ecclesiastical and civil history of the country. The work begins with the Deluge, Anno Mundi, 2242, and ends in 1616 A.D. It covers about 4,500 years of a nation's history in 1,100 quarto pages. No perfect copy of the autograph is known to exist. Trinity College, Dublin, has a portion from 1335 to 1603, and T.C.D. has a portion from 1170 (imperfect) to 1616 (ed. *J. O'Donovan*, Dublin 1851). Surviving Gaelic literature amounts in volume to many times that of classical Rome, and was an important factor in European literary history.

We can deal only briefly with the Latin *Annals of Ireland*. We know the name and station of some of the writers, and approximately their date. *Clyn's Annals* were written by John Clyn, a Franciscan friar in the convent of that order in Kilkenny; in 1336 he was guardian of a Franciscan house founded by James, earl of Ormonde, in his earldom of Carrick. His description of the plague of 1348 is simple and pathetic, and the concluding lines of his *Annals* are also pathetic: "I leave parchment for continuing the work, if haply any man survive." He died the next year. From the Scottish invasion of 1315 to the plague of 1348 may be considered the period of *Clyn's Annals*. (See *Annals of Ireland* by John Clyn and Thady Dowling, with *Annals of Ross*, edited by R. Butler, Irish Archaeological Society, Dublin, 1849). The *Annales Hiberniae* were compiled about 1537-1539, probably by James Grace, who is said to have belonged to the Priory of St. John, in Kilkenny; they begin at 1074 and end at 1370 (the manuscript, in Trinity College, was published by the Irish Archaeological Society, Dublin, 1842). For an account of the enormous output of literature and chronicles by Irish scholars it must suffice to refer the reader to *Eugene O'Curry's Lectures on the Manuscript Materials of Ancient Irish History* (1860). The authors of most of the other Anglo-Irish Annals are unknown; they express no personal feeling and record events almost mechanically. A brief list of the Annals will suffice: *Clonenagh* in Laoighis; *Cong*, of the 10th century, an account of Irish families, kings, and Irish saints; *Mellifont*, 1142-1500; *Multifernam*, West Meath, Franciscan Monastery, 1245-1274; *Nenagh*, County Tipperary, Franciscan, 1336-1370; *Duiske*, County Kilkenny, Cistercian Monastery, written in 1512 and continued to the suppression of the monasteries about 1540.

Lay Schools.—Nearly all the professional physicians, lawyers (brehons), poets, builders, and historians were laymen. A large proportion of the men chronicled in the Irish Annals during the whole period of Ireland's literary pre-eminence, as distinguished in art and general literature, were laymen. The old schools taught by Christian ollaves or doctors—laymen—the representatives of the druid teachers of ancient times, still held their ground. There were several classes of these schools. In the bardic schools were taught poetry, history, and general Irish

literature. Some were for law and some for other special professions. Edmund Campion, in 1571, saw schools for law and medicine where "they speake Latine like a vulgar tongue, whereat they begin as children and hold on sixteene or twenty yeares." The position of the bards was well established in the earliest tradition of the Irish polity. In the Anglo-Norman period, after the invasion of 1170, the Normans built monasteries where education was given as in the English monasteries, but the Irish chieftains continued their private schools of law, medicine, poetry, and history, and their output of Gaelic literature. Those schools were hereditary, passing from father to son, and lived on wherever independence was retained or where the invaders were assimilated. The later bardic schools of poetry date from about the 13th to the middle of the 17th century; they produced a plentiful supply of manuscript material, but very little has been published. The time is not yet ripe for a proportioned survey of it. One of its most remarkable features is that it deals with a continuous Irish historical present; the same manner of life, the same mode of thought, were apparent in the 18th as in the 8th century—the Gaelic Catholic civilization. Every chieftain had an annalist or bard in his school of poetry and history; we have a long list of the chief bardic families. The greater chiefs had each, severally, a law school, and we know the names of the great lawyers for the interpretation of the ancient Brehon law. The training course for a lawyer lasted 20 years. Each chief had a doctor hereditary in the family, and again we have the names. These schools were supported by grants of lands from the Irish chiefs.

A few words about the English policy in education in Ireland will not be out of place. In 1320 Pope Clement V made an effort to erect a *Studium Generale* in Dublin as a center of higher studies for the whole of Ireland. The project was doomed to failure from the start, as the pope did not realize Irish conditions and that a university in Dublin would be confined almost exclusively to the English settlers. In the Tudor period (from 1485) the shadow of impending change fell upon the Irish schools, yet at this time the O'Clerys of Donegal (the family of the principal member of the "Four Masters"—the Annalists) kept three schools—for literature, history, and poetry. During the Reformation period, Henry VIII tried in 1537 to set up an English school in Dublin as "the Irish language kept many of his Irish subjects savage and wild," but the scheme ultimately failed as funds were not available. Yet, in 1540 Henry suppressed three religious houses: the Convent of the Canonesses of St. Augustine of Grace Dieu (north County Dublin), founded in 1190 for the education of the young ladies of the Pale in the English tongue; the Cistercian Abbey of St. Mary's; and the Cathedral Chapter of Holy Trinity (Dublin), where the boys of the Pale were educated. The lord deputy and council of Ireland had recommended in vain that they be spared, as there were no other schools to take their place. The confiscation of Irish and Anglo-Norman Catholic schools went on apace. In the reign of James I a few schools in the Irish-speaking districts managed to continue, especially in Galway, where a flourishing academy for classics and general education was kept by the celebrated John Lynch, afterwards bishop of Killala. In 1615 James' commissioners visited the school, which they found full of scholars from all parts

of Ireland and "highly efficient," yet they ordered it to be closed. In spite of the penal laws many schools struggled to exist, but ended up as "hedge schools."

Medical Schools.—In the pre-Christian period in Ireland the Druids ranked next in importance to the kings. They were priest-physicians and teachers. In the early Christian or monastic period medicine was taught and practiced by the monks in their schools. The great libraries of Britain and the Continent contain numerous manuscripts that show that the monks were diligent students of medicine. As early as the 6th century the Irish monks had established on the Continent *Hospitalia Scothorum* (Irish Hospitals). Medicine and surgery were carefully studied in Ireland from the very earliest times. The kings and the great Irish families had physicians attached to their households whose office was, as in other professions, hereditary. In the 10th century the physicians, like the rest of the community, took family names: there are abundant notices in Irish writings of the household hereditary physicians of most of the leading chiefs. The stipend usually consisted of a tract of land and a residence, free of rent and tribute, together with certain allowances. The Irish medical manuscripts were written on vellum. The members of each medical family had generally their own special book, which was handed down from father to son. Other books were copied from time to time, so that the chief medical families had libraries containing the medical knowledge then available. The oldest medical manuscript in Ireland appears to be one copied in 1352. The manuscripts between the 13th and 18th centuries, preserved in the libraries of Dublin, London, and Oxford, form a collection of medical literature in the Irish language which is probably the largest in existence in any one tongue. There are 80 medical manuscripts in the Royal Irish Academy, Dublin, some of which have been published.

The physics and psychology of Aristotle were the foundation on which the medical physicians raised the structure of their study of the pathology of body and mind. Further, the school system of the scholastics was taken over *in toto* by the medical schools and, as the formal logic of the schools was adopted in the disputations and writings of the medical faculties, the study of scholastic logic was an essential part of the medical discipline. This new medical learning was introduced into Ireland in the 14th and 15th centuries. The Irish doctors took over as a whole the medical system and tradition of their continental brethren. This explains the presence in Irish medical manuscripts of philosophic treatises that were considered by the continental doctors necessary to the scientific study of medicine. There are Gaelic versions of the standard textbooks, and it is known that some of the Irish medical men had studied medicine outside Ireland. The number of extant Irish texts is considerable, but the study of this medico-philosophical literature has been almost entirely neglected up to the present time. There are manuscripts of the type in Trinity College, Dublin; British Museum; National Library, Dublin; National Library, Scotland; Bodleian Library, Oxford; University of Edinburgh; and the Royal Irish Academy. Under James I these hereditary practitioners were stripped of their holdings and followed their liege lords to foreign lands; many of them never returned to their native land but gained fame abroad.

Art Schools.—In the 5th century St. Patrick kept in his household artists in several mediums. The pastoral staff was of wood and of small size—practically a walking stick with an ornamental case. Its manufacture seems to have formed a regular branch of Irish monastic art. We still preserve beautiful specimens of these richly adorned staffs—such as that of Clonmacnois (in the National Museum, Dublin) and that of Lismore (in the Castle). Two processional crosses, that of Cong (National Museum) and that of Clogher (at Monaghan), were of oak covered with bronze designs, enamels, filigree work, and precious stones, and date from the 12th century. The two-handled chalice of Ardagh (National Museum), of about the 8th-10th century, was composed of gold, silver, bronze, lead, enamel, glass, amber, and mica. The relic shrines, preserved, are similarly precious. Some of the leather satchels for carrying those shrines around are also preserved. The Irish artists nowhere displayed more manual dexterity, ingenuity, and invention than in the art of copying and adorning religious manuscripts; they are the fairest specimens of calligraphy and illumination now extant. We need only mention the celebrated *Book of Kells* (8th century). As to church building, the two finest monuments of Irish Romanesque style are the Cathedral of Clonfert (County Galway) and Cormac's Chapel, on the Rock of Cashel (County Tipperary). The latter marks the zenith of the Hiberno-Romanesque style (1134). In artistic iconographic stone-carving of monumental high crosses, Ireland was especially rich; about 55 still remain from the 8th-10th centuries. In the 10th and following centuries Celtic crosses attained a high degree of beauty and wealth of ornament. In music, the Irish teachers continued their art in spite of the Danish invasion. In 1185, Giraldus Cambrensis, the famous Anglo-Norman writer on Ireland, stated that Irish music had "a singular charm, quick and lively, and withal sweet and blithe in tone." He mentioned especially the harp, that was probably used in the monasteries as part of the ritual. He stated that "the bishops, abbots, and saints of Ireland were wont to carry their harps with them on their journeys, and that the sounds they drew from them were a source of pious delight." Again, he stated that the Irish harpists "are incomparably more skilful than those of any other nation I have ever seen." For centuries after the time of Giraldus, music continued to be cultivated uninterruptedly in the Irish schools, and there was an unbroken succession of great professional harpists which continued to the 17th century, and after.

MYLES V. RONAN,
Parish Priest; Member, Royal Irish Academy;
Fellow, Royal Historical Society.

IRISH SEA, the body of water between England on the east and Ireland on the west. It is connected with the Atlantic Ocean on the north by the North Channel, and on the south by Saint George's Channel. The north shore of Wales and the southwest shore of Scotland are washed by this sea. It is almost circular in form, about 140 miles north and south, and the same east and west. Morecambe Bay is the largest arm of the sea on the coast of England; and on the west coast, Dublin and Dundalk bays are the most important. The Isle of Man lies in the center of the sea. The ancients termed the Irish Sea *Oceanus Hibernicus*.

IRITIS, i-ri'tis, inflammation of the iris of the eye. There are several types of the disease, depending upon the cause. Rheumatism and syphilis frequently result in plastic iritis, and the contraction of a fibrinous exudation deforms the iris. In spongy iritis, a fibrinous coagulum takes place in the anterior chamber of the eye. Catamenial iritis may occur at menstrual periods.

IRKUTSK, ir-kōōtsk', city, Soviet Russia, capital of the Irkutsk Region, in the southern part of Asiatic Russia, on the right bank of the Angara River 45 miles from the southwest shore of Lake Baikal. Prior to the Revolution of October 1917, it was the residence of the governor general of eastern Siberia and the seat of an archbishopric of the Greek Orthodox Church. A great fire in 1879 destroyed many important buildings, including the library and museum of the Siberian section of the Russian Geographical Society. There are a university, founded in 1918, and several colleges. Varied manufactures include machinery for the Lena gold fields. The city was founded in 1652 as a center for trade in fur and skins with Siberia, and commerce with China increased its importance. John Ledyard (q.v.), the American traveler, described Irkutsk as a settlement of some 2,000 houses; he was arrested there on Feb. 24, 1788, on the instructions of Empress Catherine II (Catherine the Great). Between 1918 and 1921 the city was the scene of much disturbance. A Czechoslovak force fighting on behalf of the Allies occupied it on July 8, 1918; it was soon lost to the Bolsheviks, but was recaptured on August 17. Admiral Aleksandr Vasilievich Kolchak, counterrevolutionary leader, retreated to Irkutsk after the fall of Omsk in 1919; here he was forced to resign on Jan. 4, 1920, and on February 7 he was captured and shot by the Bolsheviks. Pop. (1939) 243,380.

IRNERIUS, ir-nēr'i-ūs, or **WARNERIUS**, or **GUARNERIUS**, Italian jurist: b. Bologna, 1050?; d. ?1130. Regarded as an authority on the Justinian Code, he wrote *Summa Codicis*, the first systematic treatise on Roman law.

IRON, Ralph, the pen name of Olive Schreiner (q.v.).

IRON. The chemical element iron, methods of iron manufacture, the origin, distribution, mining, and handling of iron ores, the metallography of iron and steel, and the iron and steel industry are discussed under the following headings:

1. CHEMICAL ELEMENT IRON AND ITS PROPERTIES.—The term iron has such a variety of applications in referring to the many alloys of which iron is a base, that it is difficult for the average person to use the term correctly. Iron has been known from prehistoric times. Molding records, decaying monuments, fabulous legends, and sibylline traditions have been examined, but no one has found out how man discovered the utility of iron, or how man first learned the art of extracting the metal from its ores. The name iron undoubtedly was applied to this metal after man had discovered how to extract or separate it from its ores, and the name for iron differed in every language. The term *ayas* in Sanskrit was shared in common with copper by the Latin and Teutonic languages—Latin, *oes*; Gothic, *aiz*. Apparently the term *ayas* finally assumed the special meaning of iron, being derived from the older name of copper. The Gothic *eisarn* (iron) is considered by J. and W. Grimm as a derivative form of *aiz*. *Eisarn* is changed in Old High-German to *isarn*, later to *isan*, the Modern German, *eisen*, while the Anglo-Saxon *isern* leads to *iren* and iron. In its true sense, the term iron refers to the absolutely pure form of the metallic element iron. As iron has never been produced in the chemically pure form, pure iron is merely a metallurgical curiosity. There are several methods of producing forms of iron which are nearly pure and are available commercially. These commercial forms of nearly pure iron are available to the research scientist, enabling him to carry on many different tests in an effort to determine the mechanical, physical, and chemical properties of nearly pure iron. The following account of the characteristics of nearly pure iron are based upon the results of this research. All references are to the various forms of commercially pure iron and not to the many alloys of which iron is the basic element, such as iron casting, pig iron, malleable iron, etc. These forms of iron contain large percentages of carbon and other elements; they are highly alloyed ferrous products which differ chemically and physically from the commercial forms of nearly pure iron.

The early history of iron is inextricably tied up with mythology, religion, and folk lore. The first iron to be used by primitive man was unquestionably meteoric iron (essentially an alloy of iron and nickel) which, aside from having potentialities as a tool or weapon, possessed two characteristics that impelled those primi-

tive people to worship it. First was the desire of the people to have as a fetish some object of supernatural origin to be the abode of a spirit and thereby give to its possessor power over such a deity. Second, this fetish object must be readily transportable so that in times of stress or danger early man could have a god that was close at hand. Meteoric iron, a heaven-sent material, was an ideal fetish, because it undoubtedly came from the sky, and as a celestial visitor it was a suitable home for the spirit.

Biblical references to iron are a measure of its antiquity. There are 90 references to this metal in the Old Testament, but only 7 in the New, tending to indicate that after the birth of Christ, iron had become so common that it no longer merited unusual consideration.

Production of Iron.—With perhaps the exception of the meteoric source and a very few portions of the earth's crust, metallic iron is found in chemical combination with other elements, principally as an oxide, mechanically mixed with certain amounts of earthy matter (chiefly sand or clay), and occurring in deposits known as ore. The operation of reducing the ore to a metallic iron is known as *smelting*. The extraction of iron from some of its ores (smelting) is easily carried out, as it is only necessary to mix ores with charcoal and create a brisk fire to cause the metal to separate. If the ores are pure, the metal itself will be relatively pure and require very little if any refining. Iron produced by this process results in a pasty and unfused mass which is easily worked under the hammer and may be wrought into useful forms.

Ores.—Iron ores, from which the metal may be extracted, occur in large deposits in every continent of the globe; however, smelting operations can be carried on only in localities where iron, fuel, and flux can be assembled at moderate transportation costs. The only important varieties of ore are hematite (Fe_2O_3), magnetite (Fe_3O_4), limonite (hydrated Fe_2O_3), and siderite (FeCO_3).

Reduced Iron.—The oldest and most widespread commercial method of extraction is by reduction of iron oxide. Such oxides may be concentrated magnetite ore, with byproducts such as mill scale or partially oxidized iron scrap borings, turnings, etc. Reduction is accomplished at temperatures between 900°C . and 1090°C . in an atmosphere rich in carbon monoxide or pure hydrogen. Nearly pure iron has been produced by numerous processes involving the use of crushed ore and removal of the oxygen from the iron by use of carbonaceous or reducing conditions. This method is not new, as primitive man produced iron in this manner. Iron produced by the reduction process is often referred to as a sponge iron, from its spongelike character. Sponge iron has been almost exclusively used as a melting stock for electric furnaces as a raw material or base for the production of high grade steels. It is also a raw material for the production of an iron powder or iron in a finely divided state. Such iron powder may be used in the fabrication of iron or iron alloy parts by the technique of powder metallurgy, whereby iron powder or alloyed iron powders are cold pressed in steel dies to the shape desired. This cold-pressed shape is then heated, sintering the pressed powder together to form a solid resembling a cast or forged part.

Carbonyl Iron.—A very pure form of commercial iron may be produced by allowing carbon monoxide gas to pass over sponge iron at suitable temperatures and pressures, forming an iron carbonyl that is liquid at room temperature. The iron carbonyl decomposes to form again both the metal and carbon monoxide at higher temperatures and atmospheric pressure. Iron produced from iron carbonyl is nearly pure, containing less than 0.0007 per cent carbon and less than 0.01 per cent oxygen. Other elements may not be present in quantities that can be determined. The relative purity of this form of iron makes it ideally suited for the manufacture of magnetic cores. In powder form it is also used in the field of powder metallurgy.

Electrolytic Iron.—Electrolytic iron, prepared by electrolytic deposition, is as pure a form of iron as may be obtained by any method. There are two processes used for making iron by the electrolytic process. In one the anode consisting of metallic iron is arranged so that the electric current flows from the iron anode, which furnished the iron, through an electrolyte composed of ferrous chloride (FeCl_2) and then to a revolving rod or sheet which forms the cathode. The pure iron is deposited on the cathode in the form of a tube or sheet and can later be stripped from it. In another process iron is deposited from a solution obtained by leaching iron sulphide ore. A graphite anode permits the current to enter the solution. This is the only known commercial method of producing iron from sulphide ore. Electrolytic iron, when deposited by the usual methods, is brittle because of the hydrogen present in the iron. In this brittle form it can easily be broken and made into a powder iron. By heating the deposited electrolytic iron to a red heat (annealing), the hydrogen is driven off, and the iron becomes ductile, the ductility increasing with the temperature of annealing or with repetition of the operation. Electrolytic iron may be used in powder form for the powder metallurgy fabrication field, or remelted and cast into useful forms, or cast into blanks or ingots for rolling or forging. As a raw material, it may be used as a base for the manufacture of high-grade ferrous alloys.

COMPOSITION OF ELECTROLYTIC IRON

	Per cent
Carbon	0.006
Phosphorus	0.005
Sulphur	0.004
Silicon	0.005
Total impurities	0.020

Ingot Iron.—Ingot iron is the product of the basic open-hearth furnace, the careful manipulation of which produces a commercially pure iron. In order to keep the iron as free from impurities as possible, only carefully selected raw materials are used. The practice used in melting and refining is about the same as for ordinary steel practice with the basic open-hearth process; during refining, however, further purification is carried out by adding a pure ore to the heat in order to oxidize the small amounts of silicon, manganese, and carbon left in the bath. The molten metal is then degasified, tapped into ladles, and cast into ingot molds, forming cast ingot iron. Ingot iron is also known

as open-hearth iron. It is used in sheet metal and plate work, such as roofing, pipe, and tanks; as a base for vitreous enameling; and in electrical work, since its electrical resistance is low because of its purity.

A TYPICAL ANALYSIS OF INGOT IRON

	Per cent
Carbon	0.012
Manganese	0.017
Phosphorus	0.005
Sulphur	0.025
Silicon	0.002
Total impurities	0.061

Physical Properties of Iron.—Since the structure and properties of iron are strongly influenced by the kind and amount of impurities present in the different forms produced by the various commercial methods, it should be appreciated that the following discussion concerning the nature of iron and its behavior is based on information made available from research carried out with the various forms. Complete agreement as to the exact values for the various properties and characteristics is not to be expected. The following physical properties are averages of many different tests made by different specialists on the available commercial forms of pure iron:

PHYSICAL CONSTANTS OF IRON

Chemical symbol	Fe
Atomic number	26
Atomic weight	55.85
Density, grams/cm. ³ at 20°C. (68°F.)	7.87
Density, pounds/inch. ³ at 68°F. (20°C.)	0.284
Atomic volume	7.1
Melting point, ° C.	1535
Boiling point, ° C. (760 mm. pressure)	3000
Specific heat, calories/gram/° C. at room temperature (equals Btu./pound/° F. at room temperature)	0.1075
Latent heat of fusion, calories/gram.	65
Latent heat of fusion, Btu./pound	117
Linear coefficient of thermal expansion /° F. at room temperature. $\times 10^{-6}$	6.6
Linear coefficient of thermal expansion /° C. at room temperature. $\times 10^{-6}$	11.9
Thermal conductivity, calories/cm. ² /cm./° C./second at room temperature	0.19
Electrical resistivity, microhm-cm.	9.8
Modulus of elasticity (tension), pounds per square inch $\times 10^8$	30

Nuclear Structure.—The nucleus of the iron atom consists of 26 protons and 30 neutrons equal in number to the atomic weight of iron (56). The proton is the basic constituent of atomic nuclei having a positive charge. The nucleus of the iron atom therefore carries a 26-fold positive charge, and is surrounded by enough electrons (26; unit of negative electricity) to make the atom electrically neutral. The ratio of the weight of the iron atom (56) to the number of neutrons (30) is 0.536. This quantity is an indication of nuclear stability, which is quite large for iron.

Arrangement of Electrons.—The 26 outer electrons are believed to be distributed on four shells as follows: the inner *K* shell, 2; *L* shell, 8; *M* shell, 14; and the outer *N* shell, 2.

Crystallographic Properties.—Iron is found to crystallize in the cubic system with the possibility of existing in two different arrangements

of the atoms; body-centered cubic for alpha, beta, and delta iron, and face-centered cubic arrangement for gamma iron. The body-centered cubic arrangement of atoms consists of 9 atoms, 8 atoms of which form the 8 corners of a cube, with the 9th atom located at the center of each unit cube. The face-centered cubic arrangement consists of 14 atoms, 6 of these being placed in the center of each of the 6 cube faces.

Transformation Points.—Iron, upon solidification and during subsequent cooling to room temperature, undergoes polymorphic changes or alterations in crystal structure. The changes that occur during cooling from the temperature of solidification to room temperature reverse themselves upon heating. The temperatures at which these polymorphic changes occur have been called "critical temperatures," and are designated by the notation A2—A3—A4. Upon heating, the changes occur at 770° C. for the A2 transformation, 910° C. for the A3, and 1390° C. for A4. Below the A2 transformation temperature (770° C.) iron exists in the alpha, body-centered form, between A2 and A3 in the beta, body-centered form, between A3 and A4 in the gamma, face-centered form, and between A4 transformation and the beginning of melting, in the delta, body-centered form. These polymorphic changes are influenced by changes in pressure at a constant temperature just as the changes in melting and boiling are affected by changing pressures. The properties of one polymorphic form of iron will differ from those of another form. For example, gamma iron can dissolve up to 1.7 per cent carbon, whereas alpha iron can dissolve only 0.03 per cent carbon. These remarkable polymorphic changes that occur during heating and cooling of iron account, in no small measure, for the importance of iron as the "master metal," and contribute largely to the heat treatment effects obtained in the operation of hardening of steels.

Electrical Properties.—The most predominant electronic property of metals is electrical conductivity. The explanation of this property is based on the conception that electrons are furnished the iron, through an electrolyte com-free to move throughout the atomic space-lattice at definite energy levels while holding the positive atomic nuclei together. This freedom of movement of electrons provides a means by which a stream of electricity may be conducted through a crystal by the application of an external potential which accelerates the electrons and causes them to flow in the direction of the positive side of the applied potential. Electrical resistance arises from any condition which tends to hinder this transfer and flow of electrons. The electrical resistance of iron is greatly influenced by impurities and by previous thermal and mechanical treatment, so that the reported values for iron are often discordant. A value of 9.8 microhm—cm. at 20° C. is considered by H. E. Cleaves and J. G. Thompson to be the best approximation for the resistivity of iron. The electrical resistivity of iron, like other metals, changes with temperature. Cold deformation of the iron crystals increases the resistivity.

Magnetic Properties.—Nearly pure iron is a most important magnetic substance and is capable of being magnetized very highly when surrounded by a solenoid of wire conveying an electrical current, the iron forming a solecore.

Magnetization persists only while the current is flowing, for upon cessation of the current, iron retains a negligible amount of magnetism. It is this property of temporary magnetization that makes iron a valuable material for cores of electric magnets or solecores, the action of which plays such an important part in telephone, telegraph, relays and instruments' of all kinds. It is also used in the manufacture of magnetic chucks, clutches, and separators of all kinds. The magnetic properties of iron, like the electrical properties, are sensitive to small changes in treatment and amount of impurities. A continual decrease in magnetic properties occurs when heating iron until the A2 transformation 770° C. takes place, at which point iron loses its magnetic properties, becoming nonmagnetic; however, it regains its magnetic possibilities upon cooling again. The temperature at which this loss of magnetism occurs is known as the *Curie Temperature*, one of the most interesting phenomena exhibited by the metal iron.

Mechanical Properties of Iron.—Commercially pure iron is a relatively soft, ductile metal which cannot be hardened by any heat treatments such as are applied to steels. Owing to its high ductility, it can be formed cold by drawing, rolling, stamping, or bending. Any cold forging or forming is accompanied by an increase in hardness and strength. Impurities and alloying elements such as carbon greatly alter the mechanical properties of iron. The element carbon, more than any other constituent, affects the properties of iron, and changes iron to steel. The following indicates the mechanical properties that can be expected from ingot iron which has been annealed to produce a dead soft condition:

Tensile strength in lbs. per sq. in.....	38,000
Yield strength in lbs. per sq. in.....	19,000
Ductility as measured by percentage elongation in 2 in.....	43 to 48
Per cent reduction of area.....	70 to 77
Hardness as measured by the Brinell Hardness Test	67 Brinell

The mechanical properties of iron may be increased by cold deformation or cold work-hardening. The tensile strength of ingot iron may be increased to approximately 100,000 lbs. per sq. in., with the Brinell hardness increased to approximately 220 Brinell, by subjecting it to severe cold working. Cold working is the only practical way in which the mechanical properties of commercially pure iron may be changed, as this metal is not susceptible to hardening by heating and quenching as is the case with such iron-carbon alloys as steel. The only heat treatment that is carried out with commercially pure iron is that of annealing after cold work-hardening. Annealing may be done by heating the cold work-hardened iron to a temperature range from 650° C. to 750° C. followed by cooling to room temperature. This treatment will restore the original soft, ductile condition of the iron.

Corrosion of Iron.—The metal iron is silverlike in color, and when freshly polished or burnished acquires a bright metallic luster. Iron under ordinary conditions at room temperature in air tends to rust. The tendency of iron to corrode in air is its most unfortunate property. The fact that the structure of iron, un-

less protected, tends to disintegrate into a red powder causes us to spend millions of dollars annually to avoid destruction of objects of iron. But the process of rusting, although familiar, is not simple. It is not merely the union of oxygen with iron to form the oxide Fe_2O_3 . The rust is a hydrated oxide of varying composition, to which we may assign the formula $3\text{Fe}_2\text{O}_3 \cdot n\text{H}_2\text{O}$. Pure iron tends to rust slowly; the greater the amount of some impurities present, the more rapidly the process takes place. Furthermore, iron does not rust in the absence of water; even if water is in contact with it, the process is not particularly rapid if that liquid is pure. Aqueous solutions of electrolytes cause the action to go on with great rapidity, as anyone can observe by watching the conduct of iron in contact with sea water. The protection of iron from rusting involves merely the formation over the surface of a film which is impervious either to air, or to water, or to both. To attain this end, the metal is coated with zinc, tin, terne metal or vitreous enamel; or the film of magnetic oxide, formed while the iron is cooling (after hot rolling), may be left on the iron.

Polished iron, when heated above room temperature in air or steam, will oxidize by the formation of layers of iron oxide with an aggregate composition intermediate between FeO and Fe_3O_4 . Thin oxide films forming between a temperature range of 190°C . and 375°C . furnish the so-called *tempering colors* used by the old-time workmen in tempering steel. The thickness of oxide film is comparable with the wave length of light, and the films furnish a series of interference tints with the dominant color altering as the film thickens. The colors vary from a pale yellow at 190°C . through blue to a gray color at 375°C . As the layers of oxide get thicker, a dark, smooth film is formed, until at a high temperature (1000°C .) a blistering effect occurs. When iron has been exposed to a temperature around 700°C ., the smooth, surface film of oxides will offer good resistance to subsequent rusting at room temperature.

Oxides of Iron.—There are three definite oxides formed from the combination of iron and oxygen: iron monoxide, or ferrous oxide, FeO ; ferrosic oxide, Fe_3O_4 ; and ferric oxide, Fe_2O_3 . Ferrous oxide, FeO , may be prepared in a number of ways, many of which involve some form of oxidation of iron at some elevated temperature between 200°C . and 700°C . When prepared by gaseous reduction, FeO is a black powder. Ferric oxide, Fe_2O_3 , occurs in the native form as hematite (ore), and if prepared artificially, ferric oxide is the end product of the oxidation of iron, of its lower oxides, or hydroxides, and many of its salts. Ferrosic oxide, Fe_3O_4 , is a black, magnetic oxide which occurs in nature as the mineral magnetite, one form of which is termed *lodestone*. Fe_3O_4 may be prepared, artificially, by oxidizing iron at a high temperature, either in air or in steam, or by heating carbonate of iron to 350°C ., in a current of carbon dioxide.

Although the compounds of iron are of far less importance than the metal and its alloys, there are numerous essential industrial processes in which compounds of iron are employed. The compound salts of iron belong to two classes: the ferrous compounds, and the ferric compounds. The former are generally green in color. They may be changed rather readily to

the ferric salts by oxidizing agents, and even tend to undergo that change spontaneously when they are exposed to air. Ferric compounds are usually red or yellow in color and are stable in air, although they may be changed by energetic reducing agents to the ferrous varieties.

Ferrous Salts.—The most common ferrous salt is the sulphate $\text{FeSO}_4 \cdot \text{H}_2\text{O}$, sometimes called green vitriol or copperas. It is obtained in large quantities as a byproduct in the process of galvanizing or tinning iron and steel to remove scale. The metallic surface to be coated is cleaned by dipping the metal into a bath of sulphuric acid. The action of the acid on the scale produces most of the sulphate, and the superficial attack of the metal produces the remainder. The sulphate accumulates in the bath from which it may be obtained by crystallization. It is a green crystalline salt which tends, upon storage, not only to effloresce, but to oxidize to the brown, basic ferric sulphate. It is used in the manufacture of inks, in dyeing, as a disinfectant, and in water filtration.

Ferric Compounds.—Ferric chloride, $\text{FeCl}_3 \cdot \text{H}_2\text{O}$, is a yellow salt, which gives, by hydrolysis, an acid reaction when dissolved in water. In an alcoholic solution, tincture of iron, it is used as a medicine. Ferric oxide, Fe_2O_3 , is much used as a cheap but effective red pigment (Venetian red), and, in another form, as the most expensive rouge. Its color varies with its purity and fineness.

Iron salts have long been used in inks. A common variety is that made by mixing a solution of ferrous salt with tannic acid. Ferrous tannate is soluble and nearly colorless, and the ink is given bluish color by addition of a dye.

Complex Cyanides of Iron.—A yellow crystalline salt, potassium ferrocyanide, $\text{K}_4\text{Fe}(\text{CN})_6 \cdot 3\text{H}_2\text{O}$, is obtained from heating nitrogenous organic matter, potassium carbonate, and iron together, and then leaching the fused mass with water. By the action of strong oxidizing agents, such as chlorine, upon solutions of potassium ferrocyanide, a red salt, potassium ferricyanide, $\text{K}_3\text{Fe}(\text{CN})_6$, is obtained. Prussian blue, $\text{Fe}_4(\text{Fe}(\text{CN})_6)_3$, may be prepared by such treatment of potassium ferrocyanide, and has considerable use as a pigment and in laundry bluing.

2. OLDER PROCESSES AND DIRECT REDUCTION (SPONGE IRON).—

"Older processes" and "direct reduction" are treated together, because from the earliest times until about 1350 A.D. all the iron made in the world was produced by the direct reduction of iron from iron ore in a single step or process.

Coal being unknown, charcoal was the universal metallurgical fuel of ancient man, and iron ore was directly reduced to metal by local smiths in small, charcoal forge fires in the countries bordering on the eastern shores of the

Mediterranean Sea nearly a thousand years before the Periclean age in Greece. Many different names were given to the product of this direct process, one among others being the term "sponge iron."

One of the earliest references to the term "sponge" in connection with iron is that of the Greek historian Diodorus Siculus of the 1st century B.C., who mentions the production on the island of Elba of pieces of iron "resembling great sponges" by the melting of pieces of iron stone (iron ore) in special furnaces. The burning charcoal in these furnaces not only furnished the required temperature, but, as we now know, also served as the reducing agent needed to combine with the oxygen of the ore.

The term "sponge" was appropriate to the product obtained by heating iron ore in a charcoal fire, as the resulting porous, spongy mass of partly reduced iron mixed with melted ore and gangue looked very much like a large black sponge. The ore itself, due to its impurities (gangue), had a lower melting point than the metallic iron, and the porous, spongy appearance of the lumps or sponges pried from the bottom of a charcoal forge fire resulted from the fact that some of the unreduced ore and mineral impurities melted together, forming a slag which ran out leaving holes in an unmelted network of solid, freshly reduced metallic iron.

Earliest Production of Iron.—The first intentional production of iron probably occurred about 1500 B.C. in the area between the Black and Caspian seas, on the southern slope of the Caucasus Mountains. By 1350 B.C. the art of iron smelting had spread from this area throughout Mesopotamia, Palestine, and Egypt, and soon thereafter to the entire Mediterranean World.

Up until the middle of the 14th century, when the first iron smelting furnaces which were large enough and supplied with a sufficiently powerful air blast to be capable of producing molten or "pig" iron came into use in Europe, all metallic iron made by man was produced by the direct process, that is, sponge iron made directly from ore.

Naturally occurring forms of iron oxide (iron ore) are always more or less contaminated with foreign mineral matter, which taken together as a whole are called gangue. The gangue in iron ore is usually made up of siliceous or clayey matter, with the addition at times of some lime-bearing minerals. The object of all iron producers is to reduce the iron oxide part of the iron ore to metallic iron and separate it from the gangue. In the early direct processes, the charcoal forge fire was not hot enough to melt the reduced iron, which consequently remained solid; it was hot enough, however, to melt some of the unreduced iron ore and gangue. This mixture of gangue and unreduced ore, which had a very much lower melting point, was known as cinder, and most of it ran out from the lower part of the fire at the side or bottom of the hearth. The product was a porous lump (loupe) of soft reduced iron; it always contained some entrapped cinder, which was largely eliminated by reheating the loupe to a high forging temperature in a second forge fire and then hammering the metal, at first gently all over to consolidate it, and then more vigorously to pound the molten cinder out of the hot, malleable mass. Several reheatings were usually required.

In the blast furnace, the separation of the

metal from the slag or cinder is accomplished much more simply, as the temperature is high enough to melt the iron as well as the gangue. The metal, being heavier and not mixing with the molten slag, collects in a layer at the bottom of the blast furnace from which it can easily be tapped off separately from the lighter slag.

The Earliest Iron Furnace.—The earliest iron-producing furnace was probably a simple vertical hole a few feet deep, dug in the steep clay bank of an open hillside. The hole was uncovered at the top and had a draft hole located at the bottom to face the prevailing wind, furnishing the "blast" for burning the charcoal. It was soon learned, however, that a stronger blast than that obtainable in this way was necessary for effective operation, and hand or foot operated bellows were used to furnish it. It is said that, even before the advent of the Iron Age, bellows had been developed in Egypt for melting copper and bronze and precious metals in clay pots or crucibles by blasting charcoal piled around them with air to make the charcoal burn faster.

To obtain a temperature high enough to melt iron in a shaft furnace, charcoal must be burned with a forced draft or blast. The early bellows were neither large enough nor powerful enough to do this. Instead, every country developed its own variation of the charcoal forge and made iron by direct reduction of the ore without melting. All of these forges worked on the same principle, that of adding iron ore to a charcoal fire blown by a forced draft of air that was usually supplied by bellows.

Medieval Forges.—An English adaptation of the direct process was carried out for several centuries in the forests of the Weald near London in forges known as bloomery hearths. These consisted of circular mounds built up of alternate layers of charcoal and ore and covered with clay. When a mound was completed, it was blasted with air until the charcoal was burned out. The cinder melted and was tapped off to one side. After the mound had partly cooled down, it was broken open, and a mass of 300 to 400 pounds of reduced sponge iron was removed from the bottom.

In a commoner European variation of this process a smaller batch of ore was treated in a charcoal fire on an open brick or stone hearth, the charcoal being blown similarly with a bellows, usually through a hole in the rear wall of the hearth. Charcoal and ore were fed to the fire for several hours, either in alternate layers or as a mixture, depending on the local practice, until a 50- to 75-pound lump or loupe of reduced iron formed in the lower part of the burning charcoal. After pokers had been used to pry it out, it was picked up by tongs, still white hot and dripping with cinder, and carried to an anvil to be hammered together into a rough bar or bloom as previously described. After reheating and hammering or forging in order to remove as much cinder as possible, these early sponge iron blooms were fashioned into finished bars not greatly different in appearance, chemical composition, and physical properties from modern wrought iron bars, which are made from pig iron either in the old-fashioned puddle furnace or by the modern Aston process.

A well-known early forge of this type was used for centuries on the island of Corsica, becoming known as the Corsican forge. A still

commoner type, known as the Catalan forge, was used throughout Europe; it is supposed to have originated in Catalonia, Spain. There were many other local variations of this same charcoal hearth process in different parts of the ancient and medieval world. In the United States, modern types of the Catalan forge with water-cooled hearth side plates, power-driven blower engines, preheated air blast and stacks to carry away the smoke and waste gases were still in operation as late as 1901. This was probably the last of the Catalan forges, but even as late as 1945, in parts of Africa, India, and China, small amounts of iron were still made locally in tiny blast furnaces, a few feet high, fed with ore and charcoal and blown by hand-worked bellows or hollow-log, piston air pumps.

Advent of Blast Furnace.—By the 17th century, the blast furnace process introduced two centuries earlier had already showed its superiority as a producer of iron over the earlier charcoal forge or bloomery processes owing to its much greater productive capacity. This was true even though the pig iron it produced still had to be further refined in "finery" forges to make wrought iron, and the two stages together required more fuel. The blast furnace continued to be the pre-eminent producer of iron from iron ore, neither the older charcoal hearth and bloomery forge processes nor the more modern direct reduction sponge iron processes having at any time accounted for more than a very small fraction of the total iron produced. In modern times over 99 per cent of the world's production of metallic iron is reduced from its ores in blast furnaces.

Modern Definition of Sponge Iron.—Since the early 1920's the term sponge iron has come to mean not only directly reduced sponge iron in the historical sense, but almost any kind of iron or steel made directly from ore, with the exception of pig iron made in a blast furnace. Technically, sponge iron is usually defined as iron ore or oxide reduced to metal without fusion; that is, a direct ore reduction or sponge iron process is one in which solid particles of metallic iron are obtained directly from solid particles of ore without any melting of either the ore or the iron.

Theoretical Advantages of Direct Reduction Processes.—Despite the almost universal acceptance of the blast furnace for smelting iron from its ores, interest in the possibility of producing iron direct from the ore never died out; renewed interest was particularly apparent in the 1920's and again in the early 1940's. Different direct reduction or sponge iron processes have been proposed over the years, and hundreds of patents have been issued on them throughout the world. A considerable number of them have progressed past the paper stage and have been actually tried out experimentally. This continuing attempt on the part of technical men in many different countries to develop an economical direct or sponge iron process has been due to the fundamental theoretical advantages of direct production. These are: first, the simplicity of producing a finished product from the ore in a single step; and second, the lower fuel requirement of the single step process, particularly if advantage is taken of carrying it out at low temperature with a gaseous reducing agent. Iron oxide is rapidly reduced to iron by carbon monoxide at temperatures between 1800° and

2000° F., and by hydrogen at temperatures as low as 1000° F. This contrasts with temperatures of well over 3000° F. which occur in normal blast furnace practice.

The theoretical heat requirement for the gaseous reduction of ore to metal without melting, in the solid state, is also much lower than when the reduction takes place by contact with hot carbon. This fact is well known from blast furnace operation. A smoothly running blast furnace operating with low fuel consumption is recognized as one in which the ore has been nearly completely reduced to sponge iron by the gases in the upper part or shaft of the furnace, before it has reached the lower, incandescent melting zone in the hearth. If the low temperature, gaseous reduction or sponge iron reaction in the shaft of the blast furnace is incomplete for any reason, the unreduced portion of the ore must be reduced by hot carbon in the hearth, thus increasing the fuel consumption of the furnace. It may be said, therefore, that efficient sponge iron formation is necessary for good blast furnace practice.

Commercial Sponge Iron Processes.—Outside of the very limited iron powder field, only two direct reduction or sponge iron processes are known to be in commercial production, and both are in Sweden. The older, the so-called Sieurin process, has been in operation at Hoganas, Sweden, since about 1910. A very pure ore containing 71 per cent iron is packed in tall clay pots in alternate layers with fine coal and burnt lime. The pots are stacked in a ceramic-type kiln fired with producer gas made from low-grade coal and heated to a temperature of from 1800° to 2000° F. for a period of several days. After cooling, the pots are opened and the loosely consolidated round cakes of sponge iron are removed and compressed to a specific gravity of about 5. The product contains over 95 per cent iron and is used by steel makers, particularly in Sweden, for the production of the higher grades of cutlery, tool and gun steels.

The other commercial Swedish process is known as the Wiberg process. First proposed in 1918, a 2-ton per day commercial unit was placed in operation at Sodafors in Sweden in 1930 after considerable preliminary experimental and development work. Its capacity has subsequently been enlarged. In this process, pure magnetite concentrates are first sintered into lumps and then charged into a low shaft furnace through which hot carbon monoxide gas is passed. The hot gas reduces the ore. The spent gas, containing the carbon dioxide formed by the reduction reaction, is withdrawn from the upper side of the furnace and circulated through hot coke in a separate unit to reduce the carbon dioxide again to monoxide. The coke is kept hot electrically, and the revived spent gas, after passing through it, is returned to the furnace to reduce more ore. About a fourth of the gas is burned in the upper portion of the furnace to preheat the ore.

In 1943, the Wiberg process produced between 7,000 and 8,000 tons of iron per year, while the Hoganas plant was said to be producing about 15,000 tons.

In the early 1930's, the Germans developed a Norwegian adaptation of the Wiberg process, called the Norsk-Staal process, which they operated for a number of years on high-grade, imported Swedish ore. It was reported to be tech-

nically successful and to have produced up to 30,000 tons of sponge iron per year, but its costs were too high to permit it to compete with the ordinary methods of steel production.

Another German direct process using a high-temperature rotary kiln is known as the Krupp-Renn process. This was developed to treat lean, high silica ores. The ore was fed, mixed with coal into one end of the kiln, and heated high enough to reduce and melt both iron and gangue. The result was a mixture of globules of iron, suspended in a viscous mass of gangue which was granulated by running it into water. This was subsequently crushed and the iron separated by magnetic means. Some slag stuck to the iron, so that the magnetic separation was not perfect, and the product had to be treated further.

Rotary Kiln Processes.—A number of rotary kiln sponge iron processes have been tried in the United States. The United States Bureau of Mines did a great deal of work on the reduction of iron in rotary kilns in the 1920's. The United States Steel Corporation tried out a process using three rotary kilns in sequence (one each for heating, reduction, and cooling) known as the Hornsey-Wills process, in the middle 1920's at Lorain, Ohio. In 1945, the Bureau of Mines placed in operation at Laramie, Wyoming, a large experimental rotary kiln which had a design capacity of 50 tons per day. The rotary kiln processes have had trouble producing a high-grade product due to contamination of the sponge iron by the gangue in the ore and the ash and sulphur in the coal usually used as a reducing agent.

A few other direct reduction processes have attained more or less prominence in the technical press since 1930. W. H. Smith of Detroit, Michigan, was active in the development of a process about 1930 which was carried out in vertical retorts through which a mixture of ore and carbonaceous reducing material descended slowly. The retorts were externally heated, the ore attaining a temperature between 1600 and 2000° F. Its capacity was limited by the necessity of transferring the entire heat requirement for reduction through the walls of the retorts. The inventor died before the process was commercialized. In 1943-1944 the Bureau of Mines experimented with a plant in Texas designed by Julian Madaras, using natural gas as the reducing agent. The natural gas was first partially converted into carbon monoxide and hydrogen by heating it with steam to give it more reducing power. The Madaras process was a batch process designed to reduce lump ore by passing hot reducing gases under pressure through it at approximately 1800° F. The pressure on the gas was varied between 35 and 65 pounds per square inch to aid the penetration of the reducing gas into the ore. Twelve-inch lumps of ore were approximately 85 per cent reduced after about 16 hours in the reducing chamber.

Still another process was one developed by G. H. S. Anderson in the 1920's, units of which were said to have operated successfully in Japan in the 1930's. In this process a mixed layer of ore and coal was spread on a large revolving circular hearth and heated from above by closed muffle flues. In this way, the oxidizing combustion gases used to supply the heat required for reduction were prevented from coming into direct contact with the ore being reduced.

Another process known as the Brassert-Cape

process was tried out during World War II in a commercial size plant at Warren, Ohio, designed to produce 100 tons of sponge iron per day. This process utilized the hydrogen content of hot coke oven gas as the reducing agent and was distinguished from other previous or contemporary processes by its much lower operating temperature, from 1100° to 1250° F. instead of from 1600 to 2000° F. At this low temperature only the hydrogen in the coke oven gas reacted with the ore. The reducing unit was a 12-hearth Herreshoff furnace. Magnetite concentrates the size of coarse sand were fed into the top of the furnace and moved slowly downward by revolving rabble arms over each of the 12 hearths, as hot coke oven gas passed upward countercurrently. The gas was cleaned after passing through the furnace and returned to the steel mill for use as fuel. The plant attained only about one third of its designed capacity and was no longer operated after the war emergency was over, although its product was used successfully in the production of a number of trial heats of electric furnace steel.

Requisites for Successful Sponge Iron Process.—To be successful, a sponge iron process must produce a high-grade product, one containing a minimum of undesirable impurities. Nearly everything except metallic iron constitutes an undesirable impurity. Because direct reduction without melting offers little opportunity for eliminating gangue from the ore, a high-grade ore or ore concentrate must be used as raw material, lower-grade ores being left to the blast furnace. Since the development of new wet magnetic concentrating methods in the 1930's, iron ore concentrates of much higher purity than ever before have become available. American reserves of magnetic iron ore suitable for concentration are also known to be much greater than was formerly believed to be the case. These two factors are so favorable to sponge iron production that they lead one to predict that development of the direct production of metallic iron from its ores without fusion will be continued in the United States until a commercially successful process is achieved.

3. CAST IRON.—Gray cast iron (synonym: gray iron) is the most widely used of all cast materials. The term "gray iron" is derived from the characteristic gray fracture, as opposed to the lighter colored fractures of most steels. The presence of the dark graphite flakes in gray iron is responsible for its unusual fracture color or shade. Gray cast iron castings range in size from heavy machinery parts weighing well over 100,000 pounds to small castings such as piston rings weighing but a few ounces. This material finds wide usage because it combines useful engineering or service characteristics with ease and

economy in overall production. Large users include the automotive industry (major casting tonnage, cylinder blocks), municipalities (gas and water piping), machinery builders, agricultural implement manufacturers, chemical and oil industries, building and furnishing industries, railroads, steamships, and so on, down to the cast iron skillet in the kitchen. In all these fields it has been challenged by other materials—the skillet is made also in aluminum and in steel. Competitive challenges have been met by improved classes of gray iron. In some cases other materials have proved superior, while in many cases gray iron has supplanted other materials.

Foundries where iron castings are made are found in nearly all cities where the population is 50,000 or over. There are about 2,880 iron foundries in the United States. Their capacities vary from small shops melting perhaps 10 tons per day, to large establishments whose daily melt may exceed 250 tons. The total melting capacity of the iron foundry industry is about 26 million tons per year, castings production about 17 million tons.

Beside iron castings, other metals and alloys such as steel, aluminum, magnesium, brasses, bronzes and others are made in cast as well as in wrought form. The casting industry is in total the fifth largest of all manufacturing industries.

The metal industries (cast and wrought) have developed tremendously since the advent of the Industrial Revolution. Manufacture, agriculture, transportation, and communication have grown concurrently with developments in metals and in their applications. Thus the material aspects of social development are connected in marked degree to developments and progress in the metals industry.

Although archaeologists have found that ornamental iron castings were made by the Chinese about 500 B.C., it was not until the 14th century that commercial iron castings were made in Europe. Their first large-scale usage was for cannon balls, initiated at Menningen, Germany, in 1388. The first casting made in the United States was a cooking kettle, made at Lynn, Mass. in 1642. The industry soon spread among the colonies. Most early castings were intended for domestic use, such as cooking ware, stove parts, pumps, and the like. Metal used was pig iron (itself essentially a gray iron) direct from the blast furnaces. The cupola, in which most gray iron is melted today, was developed in commercial form by an Englishman, John Wilkinson, in 1794. The first cupola in America was one built in Pennsylvania about 1820.

Like steel, gray iron is an alloy or series of alloys containing various percentages of iron, carbon, and other elements. As distinguished from steel, gray iron has a high total carbon content and low ductility. The greater proportion of the carbon in gray iron is in the form of graphite.

Defined technically, cast irons are alloys of iron and carbon containing so much carbon that as cast they are not appreciably malleable. Usually from 1.7 to 4.5 per cent carbon is present, and, in most cases, an appreciable percentage of silicon. All cast irons are eutectiferous alloys, and are classified commercially as follows: (1) pig iron (blast furnace product; see section on *Pig Iron*); (2) white cast iron (a hard, not graphitized product); (3) malleable cast iron (see

article 6, *Malleable Iron*); (4) gray cast iron.

Gray cast irons as cast have combined (cementitic or carbide) carbon not in excess of an eutectoid percentage (usually approximately 0.8 per cent carbon). The usual total carbon percentage is in the range 2.70 to 3.60 per cent. Percentages of graphitic or free carbon may range from about 1.90 to possibly 3.50 per cent.

All gray irons contain considerable percentages of silicon, usually in the range 1.0 to 2.8 per cent. They also contain appreciable percentages of manganese and phosphorus, and small percentages of sulphur.

A considerable tonnage of gray iron, called alloy iron or alloyed gray iron has elements such as nickel, chromium, copper, molybdenum, etc., added to enhance or modify its mechanical and manufacturing properties.

"Semisteel" is a term which has been used for gray irons of actual or supposed better mechanical properties than the average gray irons. Material sold under such a name does not have the ductility and high impact characteristics of steel—it is true gray iron. In better informed engineering circles the term "semisteel" is obsolete. A wide variety of strength classes is available under gray iron specifications. The engineer wisely and safely prescribes the strength class required, and is not misled by misnomers, such as semisteel and various trade names which sometimes imply that a true gray iron product is something else.

Usual gray irons are magnetic, and of ferritic base. Some very highly alloyed irons, called

FIG. 1. Vertical section through cupola furnace for producing gray iron.

austenitic irons, are practically nonmagnetic and have markedly enhanced resistance to numerous corrosive fluids.

MANUFACTURE

Melting Practice.—Gray Iron (*Cupola Practice*).—The major portion of the gray iron produced in this country is melted in the cupola furnace. The cupola is a vertical, cylindrical type of furnace consisting of a steel shell lined with fire brick (Fig. 1). The furnace is charged through a charging door which is located 15-20 feet above the bottom plate. At the lower end of the furnace is the wind box, or air chamber, as shown in the diagram. Air enters the cupola through the tuyeres. The cupola is a simple and an economical melting unit because the fuel and

the metal are in intimate contact with each other.

Fuel, metal, and flux are charged through the charging door of the cupola. Coke is charged first and the initial charge is known as the bed charge. Iron is then charged upon the coke. Alternate layers or charges of coke and iron are introduced into the cupola. Where flux is used it is charged on the coke. The coke bed is ignited by means of kindling wood or an oil torch. The bed charge of coke usually extends from 28-50 inches above the top of the tuyeres.

The charge of iron depends upon the capacity of the cupola. The cupola sizes are referred to as the inside diameter of the lining of the cupola. Cupola sizes may range from 18 inches in diameter to over 100 inches. The size used for ordinary commercial practice varies from 42-84 inches in diameter. The rated capacities on these sizes are from 5-25 tons of metal melted per hour.

The quantity of coke used depends upon the quantity of metal charged. The bed charge is a definite height above the tuyeres. Consequently, this portion of the coke goes in by volume instead of by weight. The succeeding charges of coke are in direct proportion to the metal charged. This proportion varies from one part of coke to 7-12 parts of iron.

The metal charged into the cupola consists of gray iron scrap and pig iron. Steel scrap is also used where strength of the finished casting is important as steel scrap increases the strength by modifying the composition of the iron. The proportions of gray iron scrap, pig iron, and steel scrap are governed by the type of casting. It is customary to find considerable difference in mixture of metal used, even among foundries making the same class of work.

Limestone is used as a flux in cupola operation. The purpose of the flux is to form a slag with the dirt, impurities in the metal, and the coke ash. Fluorspar (calcium fluoride) is sometimes used as a fluxing agent in combination with the limestone. The purpose of the fluorspar is to thin the slag and also to aid in the removal of sulphur, although correct proportions of limestone will ensure a fluid slag and some sulphur removal. Various forms of soda ash are used as fluxes, particularly in the ladle. Proper slagging improves the quality of the iron.

The air is introduced into the cupola through the tuyeres. Usually, the introduced air is at room temperature, but preheated air (hot blast) is also used. The volume of air introduced is important and governs the melting rate of the cupola. The air is used in the combustion of the coke, which in turn melts the iron. Under ordinary conditions the blast pressure will vary from 8-20 ounces per square inch, depending on the cupola height, number of charges, and character of charged stock. Some of the larger production foundries have increased blast pressures to 30 ounces per square inch, in order to obtain greater capacity from the cupola.

Devices are available which permit control of the weight of air entering the cupola. This method is more accurate from the standpoint of control than is the measurement of the air volume.

The metal mixture entering the cupola is governed by the composition of the metal desired for the finished castings. Pig iron is the base of the charge. Charges are seldom made up entirely of scrap. Since the pig iron is of known

composition, the greater the amount of pig iron and the smaller the amount of purchased scrap, the more uniform is the composition of the resulting castings. For high-grade castings such as automobile cylinders, the percentage of pig iron is about 35-45 per cent of the charge, while for castings such as sash weights practically no pig iron is used.

Electric Furnace Melting.—There has been a steady increase in the utilization of electric furnace melting for cast iron. This is particularly true in the production of special cast irons. The electric furnace lends itself to a high degree of control in respect to composition and temperature. In some cases, large quantities of scrap, such as borings, can be utilized and a good grade of casting produced. The lower cost of scrap metals for the electric furnaces helps to compensate for the excess melting cost as compared to the cupola.

Two types of electric furnace are in general use: (1) three-phase direct arc; (2) single phase indirect arc of the rocking type. Good results are reported from both types of furnaces.

In some cases the electric furnace is used for the entire melting process while in other cases a duplex method is used. In the duplex method all or part of the charge is melted in the cupola and the molten metal is refined and superheated in the electric furnace. Additions of alloys and steel may be made to the metal in the electric furnace. For steady production the duplex method is usually more economical, owing to the low melting cost in the cupola.

Air Furnace Melting.—The air furnace is used to a limited extent in the production of gray iron castings. This is a hearth type of furnace, in which a refractory wall (fire bridge) near one end separates the hearth from the combustion chamber (fireplace), and a refractory wall (flue bridge) separates the hearth from the stack (flue) near the other end; a removable type of roof permits the charging of large pieces of scrap; flames from the burning fuel (coal, fuel oil, or gas) sweep across the hearth and leave through the stack. The air furnace is frequently used for the higher strength cast irons, because it lends itself to accurate control of composition, and higher pouring temperatures are obtained than with the cupola.

Molding.—A mold is a form or cavity in a refractory material, into which molten metal is poured. The shape of the cavity determines the final shape of the poured metal after cooling. Molds are made by using a pattern whose shape is essentially that of the desired casting. A refractory (such as molding sand) is packed around the pattern. The pattern is then withdrawn, leaving its imprint or shape as a cavity in the refractory. Suitable orifices (known as gates) are provided to permit entry of the molten metal into the cavity or shape.

A majority of gray iron castings is made in so-called green sand molds in which the sand is not baked before molding. The usual refractory is molding sand. This often is a natural product characterized by a silica grain base, the grains being coated by clay which occurs in natural molding sand deposits. When slightly moistened such molding sand has considerable coherence, and maintains its shape when pressed or rammed into place. It also is permeable to gases generated when molten metal is poured

into the mold.

The molding operation usually employs a two-part flask, or container for the sand and pattern, because of necessity of removal of the pattern from the sand, to leave the imprint desired.

When the casting to be made is not a solid design (such as a solid cylinder) but contains an opening through it (as a cylindrical bushing) or is a metal shell (such as a valve body), refractory cores corresponding to the inner dimensions

FIG. 2. Pattern for a pulley.

of the casting are placed in the mold cavity. The molten metal flows into the space between the mold cavity and the core, and when solidified has the desired shape and wall thickness.

A simple method of making a mold is shown in Figs. 2, 3, 4, and 5. These diagrams show, in cross section, (1) pattern for a pulley, which pattern, it will be noted, is split into two parts; (2)

FIG. 3. The drag or lower half of pattern shown in Fig. 2.

(Fig. 3) shows one half of the pattern, the drag or lower half. This is placed on a mold board, on which also rests the flask or container for the refractory molding sand. When the sand is placed therein and rammed about the pattern, the drag (lower half) is rolled over. This will be recognized as the bottom part in (3) (Fig. 4) shown with sand as dotted shading. This illustration shows the cope (or top

FIG. 4. The drag rolled over, after ramming of sand about the pattern.

half) of the pattern and flask in place, with a gate pin (a portion of the pattern) to make an orifice to receive the molten metal. (4) (Fig. 5) shows the assembled mold, after the pattern has been withdrawn, and a central core placed to make the opening in the hub of the pulley. Molten metal is poured into the opening, upper left, flows downward, then transversely through a "runner" (which has been cut into the drag) and so into the cavity, whose shape is that of the

FIG. 5. Assembled mold after pattern is withdrawn and a central core inserted.

pulley to be made. (The white or unshaded areas in Fig. 5 represent the metal sections.)

After the metal has solidified, the mold is "shaken out" and the casting removed. The "runner" is broken or cut off, and the core broken or punched out. The casting is cleaned from adhering molding sand, usually by shot or sand blasting. It then is ready for machining and other finishing operations.

Molding is an ancient art. Only in relatively recent times have scientific approaches and extensive mechanization of the operation been used. Demand for huge numbers of castings of a given design has resulted in development of largely automatic molding operations. Patterns and gating systems often are mounted on plates. The molder places a half flask on the plate. Sand from a hopper fills the flask. Pressure is exerted on the sand by an automatic device (such as a pressure plate) compacting it around the pattern and in the half flask. The pressure plate is lifted automatically. A vibratory or other device slightly loosens the pattern from the sand, then lifts the half flask (with its design imprinted by the pattern). The molder places the half flask on a conveyer. While one molder is making the upper or cope part, another may be making the drag or bottom part of the mold. If a cored job, a core-setter places the cores in position (print pattern extensions, into which projections on the cores are placed, are provided for locating and anchoring the cores). The cope halves are placed on the drag halves. When the mold halves are weighted or clamped (to keep the pressure of the molten metal from lifting the copes) the molds are ready for pouring. Ladles of molten metal are transported from the melting furnaces to the molds, and these last then are "poured off," or filled.

The handling of materials is an involved engineering problem in modern production foundries. Machinery has to a great degree supplanted

the shovel and wheelbarrow, and the hand carried ladles of molten metal.

The molten metal flows from the spout of the cupola into a ladle, which is picked up by a crane or by monorail systems and mechanically transported to the pouring floors. The molds to be filled are on a conveyer line. When metal poured into them has solidified, the conveyer takes molds (and castings) to a "shakeout" station, where sand and cores are separated from the castings. The sand is largely recoverable and is carried to mixing machines where it is "tempered" (proper moisture content restored) and rebonding materials incorporated. From thence it goes to hoppers or storage tanks. From these it is delivered again to the molders for re-use. All these operations are under technical control. Magnetic separators have taken out any metal particles. Bonding materials (such as clays, bentonite, etc.) and moisture have been added on the basis of laboratory tests which ascertain the amounts needed; mixing machines and screens break up all sand lumps, aerate and cool the sand, and place it in best physical condition for re-use.

The castings and attached gating systems are separated mechanically or manually. The gating systems (called returns) are conveyed back to the furnaces for remelting. The castings are cleaned, usually by mechanical means, such as "blasting." In blasting, a high-pressure stream of hard metal shot or coarse silica sand, or even water, quickly cleans the castings of adhering molding sand, so that they can be more readily machined.

The cylinder block of an automobile is a good example of a gray iron casting made by production methods. Such blocks are extensively cored, to provide the water jacket and cylinder bores. Examination of a broken block in a junk dealer's yard and a visit to a local foundry will prove highly informative to the interested reader.

Although the larger percentage of high-production castings are made by green sand molding, substantial tonnages are made by other methods. In dry sand molding, the refractory (natural or synthetic sand with supplementary binders) is rammed (packed into the mold around the pattern) while moist. After the withdrawal of the pattern, the flask halves are dried in an oven. Cores are then placed, flask halves closed, and molds poured. Such molds avoid problems of moisture generated during pouring (as in green sand molding), and they are stronger and better able to withstand the erosive effects of flowing molten metal and its pressure effects. As used for fairly large castings, dry sand molds allow casting of more complicated shapes.

Among methods used for producing very large castings, pit molding is typical. Instead of using a drag (bottom part of a flask), an excavation (or "pit") is made in the foundry floor. The pattern is placed therein and sand with special binder suitably packed around it. A cope flask is rammed and the pattern or pattern parts are removed from cope and drag. Such molds usually have a bonding material (such as a molasses, dextrin, or starch compound) sprayed or swabbed on the surfaces. The mold surface is skin dried by means of a torch or other heating device. Cores are placed and the mold closed (cope placed on drag).

Since pit molding is not a highly repetitive

operation, a high degree of craftsmanship is required. Loam molding also is a specialized art. Loam molds may be used for large concentric castings such as large kettles, cylinders, ring gears, etc. Instead of using full patterns, the general contours are made by use of sweeps (templates or boards having a beveled edge), and some sections made by use of skeleton and part patterns. The backing is made of brickwork, faced with a special loam sand. Faces of loam molds (and cores) are skin dried.

A considerable tonnage of cast iron pipe is made by centrifugal casting or "spinning." A cylindrical metal mold mounted nearly horizontally and faced with suitable refractory is employed. No cores are used. Metal is run into the mold, and the mold rotated rapidly. This throws and holds the molten metal against the inner surface of the mold, until solidified. The shell thickness of the pipe is controlled by the amount of metal run into the mold.

In die casting, molten metal is forced under pressure into a metal die (mold) and pressure is maintained until the metal has solidified. This method is more often used with low melting temperature nonferrous alloys than with gray iron. However, some small, intricate and highly repetitive designs have been made in gray iron. A major problem is obtaining a refractory which protects the metal die (permanent mold) from the deleterious effects of the molten metal.

The ancient "lost wax" process (as described in the *Autobiography of Benvenuto Cellini*) has been revived in what is called precision casting. The method is similar to that used by dentists in making the gold portions of a bridge. This process is rarely used for gray iron.

About 1920 molding was a highly empirical art, demanding great skill and ingenuity. Science and engineering have substituted controlled methods for much of the skill, and mechanical devices for much of the old strong-back labor.

Gray iron is a very satisfactory alloy to cast. It possesses excellent fluidity, so that intricate designs can be run. Its shrinkage (liquid) and contraction (solid) are lower than most metals. Thus it is relatively easy to get sound castings to quite close dimensions.

Metallurgical studies of solidification characteristics and control through directional solidification have promoted more logical designs and indicated the most effective ways to feed for shrinkage (that is to provide reservoirs, called risers, of molten metal which can flow into the casting during its solidification and natural contraction period and thus compensate for the contraction, which last might otherwise leave voids or "shrinkage cavities").

The most widely used refractory for molding is natural molding sand. Such natural product varies considerably. In the old days "feel" and experience were the only guides—sometimes sorry ones. Today foundries test their sands for bond (strength), permeability (ability to allow gases to escape), moisture, and grain fineness. Standards are set and technical control exercised. The desired properties are attained by the use of synthetic additions and by blending. Other refractories than molding sands have been used, for example cement. Oils (used in cores) and other binders and surface coating agencies have been studied, and means devised for testing and controlling, by laboratory methods, many of the procedures that formerly were

largely empirical. Numerous and effective as these advances have been, the foundryman and metallurgist are constantly engaged in seeking further improvements in both quality and economy.

Design and Section Size.—From the viewpoint of producing internally sound castings and relatively complicated shapes, gray iron is an excellent casting alloy. These good casting characteristics are due to its relatively low shrinkage and contraction, and to its high fluidity. However, it is highly desirable that sections of the casting are so proportioned that the sections most distant from the point or points where the casting is to be fed will solidify first, with solidification progressing toward the heads or risers, where the hottest fluid metal is located. "Progressive solidification" is highly helpful in the production of sound castings, and for this reason the design should, insofar as is possible, approach uniformity in section size. Then the

FIG. 6. Showing the relationship between tensile strength and diameter of gray iron test bar.

pouring temperatures and speeds, the arrangement of gates and risers and other controllable factors can be employed to best advantage. While designs are not limited to simple and uniform sections, the artifices that must be employed to achieve success with poor designs, from a foundry viewpoint, always add to the cost of production. In a given foundry, all types of castings made do not possess the same section size, the weights of different designs vary, and it is at times necessary to provide different section sizes in the same casting design.

In a given gray iron composition, the strength varies according to the section size into which it is cast. Gray irons are more sensitive than most alloys to differences in cooling rates, and sections of heavy castings cool more slowly than lighter ones.

Fig. 6 illustrates this effect, as determined from tests on test bars of various sizes. In all cases strength drops as bar size increases. However, the amount and degree of loss in strength is much less in the case of low carbon, alloyed, high-strength iron (top curve) than it is for the somewhat higher carbon, higher silicon metal (bottom curve). The metallurgist and designer must select suitable material not only by strength prescription, but also by the strength desired or needed in a given section. Referring again to Fig. 6, if 35,000 pounds per square inch is required, iron represented by the bottom curve is suitable only for sections represented by a test bar which is one inch in diameter. For sections that cool as slowly as the 3-inch test bar, iron possessing the characteristics shown by the top curve must be employed.

PRINCIPLES OF CONTROL OF PROPERTIES

In the case of pure metals, such as copper, lead, and silver, there is but one structural component—the crystals or grains of the pure metal. Often the possibilities of modifying mechanical properties, such as strength and hardness, are relatively limited. In cast form, some variations in grain size can be effected by differences in cooling rate, as by casting in sand (slower cooling) or into metal molds (faster cooling). Working (and especially cold working) may be used to achieve internally stressed conditions which can considerably augment strength and hardness. However, few casting designs are adaptable to further forming by deformation or working.

Many alloys have two or more structural components. Alterations in the amounts and distribution of the components can be employed to effect marked changes in mechanical properties. Such alterations can be made by variations in composition, by heat treatments, and by other means.

Gray iron is essentially an alloy of iron and carbon. The other elements present are useful in that they affect the iron and carbon structural components.

The matrix, or base metal structure of gray iron, somewhat resembles that of steel. However,

FIG. 7. Coarse graphite flakes in "open" gray iron.

gray iron contains graphite flakes. These flakes are without strength and break up the continuity of the matrix. It is the presence of graphite flakes that makes gray iron an alloy of low ductility. They also impart the characteristic dark gray fracture color, add greatly to machinability (as compared to steel) and (because they expand when the metal is at high temperature and rather plastic) lessen the contraction characteristics and enable sharper mold impressions when formed.

Fig. 8. Fine graphite flakes in close-grained gray iron.

A piece of gray iron, polished and examined under the microscope, appears as shown in Figs. 7 and 8. Fig. 7 shows coarse flakes, characteristic of weak and so-called open-grain iron; Fig. 8 shows smaller and evenly distributed flakes, characteristic of strong and close-grained iron.

To a great degree the foundry metallurgist controls the properties of the iron by controlling the amount, size, and distribution of these flakes. Moreover, he takes into consideration the matrix, particularly with respect to combined carbon (found in the lamellar structure known as pearlite) and a phosphorus-rich component known as steadite (in gray iron, largely a binary eutectic of iron and phosphorus). Factors influencing the properties of gray iron are (1) chemical composition; (2) structural and mechanical make-up of the melting charge; (3) melting process; (4) thermal and mechanical history—furnace spout to cooled casting; (5) subsequent heat treatment; and (6) design and workmanship. With factors 2, 3, 4, 5, and 6 constant, the properties depend on composition, but various foundries employing different methods may produce considerably different results with the same composition or, conversely, the same result with diverse compositions.

Chemical control is exercised largely through the elements carbon (total) and silicon and, to lesser degree, through manganese, phosphorus, and sulphur. Alloying elements such as nickel, copper, molybdenum, and chromium may be employed to modify or augment the results attainable by the preceding elements. Special modifying agencies known as inoculants may be employed in small percentages. Among these are silicides (such as calcium silicide), graphitic carbon, and various complex additions containing one or more of the following elements: vanadium, titanium, nickel, chromium, aluminum.

The furnace charge contains various percentages of pig iron, gray iron returns (gates and risers), scrap castings, and usually some steel scrap. These influence the metal not only according to their composition, but also according to their size and shape. Light pieces behave differently from heavy ones during the melting, probably because of the differences in areas exposed to combustion gases.

The operation of the cupola with respect to the amounts of coke (and its character), the weight of iron charged, the amount of air used, slagging practices, and other factors distinctly influence the mechanical characteristics of irons of given chemical composition. Likewise, iron melted in the electric furnace differs from iron of like composition made in the cupola.

Temperatures attained during melting have a marked influence on the properties of the metal,

as does the temperature at which the metal enters the mold. Gray iron is materially influenced by the rate at which it is cooled from the molten state to temperatures somewhat below the eutectoid (about 1100°F.). The size of section, the thermal conductivity of the mold, and other factors alter the microstructure and the mechanical properties of the metal.

Influence of Carbon.—An increase in total carbon content (other factors being equal) increases the graphitic carbon content, with a consequent decrease in strength, a slight decrease in indentation hardness, and an appreciable improvement in machinability. Over the usual commercial total carbon range, an increase also promotes greater fluidity and a decrease in shrinkage and contraction characteristics. The modern trend is toward lower carbon and higher silicon irons. Some of the disadvantages of lower carbon are offset by the action of silicon, and a better engineering product is attained.

Influence of Silicon.—Silicon is a graphitizing element useful in controlling the relative properties of combined and graphitic carbon. Irons with a very low silicon content do not graphitize as cast. All the carbon then occurs as an extremely hard brittle component—iron carbide, called cementite or chill. Such metal is known as white iron. It is practically unmachinable and has few direct uses.

In the production of gray iron sufficient silicon is incorporated to avoid formation of white or mottled (partially white) iron. If low strength (maximum graphite) is desired, a high silicon content with fairly high carbon is employed. If, in an attempt to get maximum strength, the silicon is decreased too much, white or chilled spots and unsatisfactory machining and engineering properties are incurred.

Besides decreasing the stability of iron carbide (and thus acting as a graphitizer), silicon lowers the percentage of carbon required for the eutectic. This effect modifies the graphite distribution in irons of like carbon but dissimilar silicon content. It is easier in cupola melting to keep the total carbon content lower in the presence of high silicon.

In commercial gray irons the silicon content rarely is allowed to exceed 3.0 per cent. Probably 90 per cent of the tonnage of gray iron castings has silicon contents within the range of 1.75 to 2.75 per cent. Certain special cast metals used for their high resistance to acid corrosion have silicon contents of about 13 to 17 per cent and carbon under 1.0 per cent. These alloys are not gray iron, for graphite is absent. They are somewhat difficult to machine and have relatively low shock resistance. Some alloys with lower silicon content (7 or 8 per cent) that contain nickel and chromium are used for heat-resisting parts, such as grates.

Influence of Manganese.—The manganese content of most commercial gray irons is within the range of 0.40 to 0.90 per cent. Manganese combines readily with sulphur in gray irons, forming a relatively harmless inclusion, manganese sulphide. Changes in manganese content within this percentage range do not have very marked effects.

Influence of Sulphur.—In the presence of sufficient manganese (0.40 to 0.90 per cent), sulphur up to 0.10 per cent, or perhaps more, is without appreciable deleterious effect on gray iron.

Influence of Phosphorus.—Phosphorus contents of most commercial gray irons are within the range of 0.15 to 0.90 per cent. Phosphorus is found in a separate structural component known as *steadite*. One part of phosphorus plus nine parts iron form about ten parts *steadite* by volume. *Steadite* itself is rather hard and brittle. Its melting point is low, about 1800° F. Up to perhaps 0.30 or 0.40 per cent phosphorus, this element is without very marked effect on gray iron. At over about 0.50 per cent phosphorus content there is enough *steadite* so that this component forms nearly continuous grain boundaries, producing a cellular or network structure in the matrix. This net work (other factors being equal) lowers the deflection (ability to bend without fracture) and impact characteristics of the iron. It affects the strength but little. Higher phosphorus also promotes fluidity. However, this effect sometimes is accompanied by a greater tendency toward shrinkage effects, hence greater attention to design and gating is needed. Under some conditions machinability is somewhat impaired. Conversely, abrasive wear resistance may be somewhat improved.

Influence of Alloys.—Since 1925 usage of so-called "alloys" or alloying elements in gray iron has grown rather rapidly. Among the more commonly used are nickel, copper, chromium, and molybdenum. In commercial gray irons these elements are useful both in helping in the control of graphitization characteristics and in strengthening or otherwise modifying the matrix structure. In high percentages (18 per cent or higher "alloy" content) new types of cast irons, the austenitic cast irons, have become available. These are relatively nonmagnetic and have a useful range of resistance to various acid and caustic corrosives.

It was estimated that in 1945 between 10 and 20 per cent of gray irons contained appreciable percentages of added alloys. In 1930 it was estimated that only about 2 per cent had such additions.

Alloying elements may be classified in two general groups—those which promote graphitization and those which restrain it by lessening the tendency of iron carbide to graphitize. The former group lessens tendency toward formation of "chill," the latter to promote the formation of chill or tendency toward hard white iron.

The metallurgist commences his control of the mechanical properties of gray iron by first regulating the total carbon content by raw materials mixture, melting process, etc. The other elements (normal and alloying) are used to control the amounts of graphitic and combined carbon, their distribution, etc.

Silicon is a powerful graphitizer. If sufficient amounts are used to ensure freedom from chill in light, rapidly cooled sections, excessive graphitization and coarse grain are likely in heavy and more slowly cooled sections of the same casting. Such nonuniformity in structure is accompanied by undesirable nonuniformity in mechanical properties. If the silicon content should be reduced to a point where proper structure is attained in the heavy sections, the lighter sections may be found chilled, hard, unmachinable, and brittle. By use of supplementary alloying elements of mildly graphitizing type such as nickel or copper, and by restriction of silicon to amounts suitable for the heavier sections, chill is avoided in the light sections. The net result is

greater structural and mechanical uniformity throughout all sections. It is fortunate that these mild graphitizers (such as nickel and copper) have relatively much less graphitizing effect in heavy sections. Furthermore, they tend to harden and strengthen the matrix in these heavy sections.

Chromium is a powerful carbide-stabilizing element. When heavy sectioned castings and light sectioned ones are to be poured from the same molten iron mixture, the silicon content is made suitable for the light sectioned castings, Metal going to the heavier ones has some chromium added. This offsets the action of silicon, which otherwise would be excessive for the purpose. In many cases it is found desirable to use complex alloy additions, for example nickel-chromium, copper-chromium, nickel-chromium-molybdenum and others, so balanced as to attain combinations of structure and properties less easily attainable by simple procedures.

Molybdenum is a mild carbide stabilizer. Suitable additions afford one of the simpler methods of increasing strength without the marked danger of encountering chill, incurred by use of more powerful carbide stabilizers. Molybdenum tends toward the production of a finer grained, stronger matrix structure. When it is used, a slight upward revision of silicon content, or the addition of a mild graphitizer (such as nickel or copper) is the usual practice.

The best foundry practice includes suitable manipulation of carbon and silicon practice first, to get the best combination of these for the purpose involved. Alloys and alloying elements are used to supplement only when necessary. Reduction of total carbon content is in itself very potent toward promoting uniformity of strength, particularly throughout medium and heavy sections. If the iron is properly processed and the normal elements are in correct balance, alloys and alloying elements, if necessary, can then be used most effectively and economically.

Controls Other Than Composition.—*Inoculation.*—It has been discovered that various substances and admixtures added to the molten iron shortly before pouring may considerably modify its structural and mechanical properties. Such substances are called "inoculants." Calcium silicide was probably the first used inoculant. Other silicon-containing substances, such as nickel-silicon and ferrosilicon, are used. Various complex alloys which may contain vanadium, nickel, chromium, copper, titanium, aluminum, molybdenum, etc., in various proportions, and even graphitic carbon have been employed. Inoculants are added in quite small amounts. Their action is different and in some respects more potent than that of additions of alloys and alloying elements previously discussed. Inoculants can and are being used in numerous cases to lessen tendency toward chill, or hard spots. In this respect they act as graphitizers. Under some conditions (especially on external surfaces) some gray irons may tend toward production of extremely fine graphite flakes in a soft or ferritic matrix. In such cases inoculants often have been found useful to produce a normal-sized graphitic structure and a desirable pearlitic matrix. (These effects are not necessarily paradoxical.) If molten inoculated iron is allowed to stand for a long period, the effects of the inoculant gradually disappear. It is thought that inoculants act as nuclei for the

formation of graphite flakes.

Superheating.—High melting temperature has marked effects on the properties of gray iron. In the case of irons of fairly high carbon content, high melting temperatures (usually in the range 2850° F. to 3000° F.) tend to retard slightly normal graphitization tendencies and to bring about finer grain and increased strength. Section sensitivity is decreased. Ordinary cupola melting temperatures are lower than the superheating range. Therefore, when superheat is desired electric furnaces are often used. Since the costs of electric melting are high, the usual practice is to melt the iron in the cupola, and transfer the molten metal to an electric furnace for superheating.

Heat Treatment.—Heat treatments of gray iron are undertaken for one of two purposes: (1) alteration of structure and mechanical properties, or (2) relief of internal stresses as set up in the casting process.

If a gray iron is heated above the eutectoid transformation range (for example to about 1550° F.), the ferrite (alpha iron) changes to gamma iron. The gamma iron is capable of dissolving the combined carbon of the pearlite, forming a solid solution known as austenite. If the metal is quenched (cooled rapidly), the austenite has not time enough to revert to the normal or pearlitic condition when passing through and below the eutectoid transformation range. A transition product, usually martensite, is formed. Martensite is hard and brittle. Its formation results in lowered strength. If, however, the metal is tempered or drawn (heated back to a moderately elevated temperature, say 750° F.), the brittle martensite is decomposed, and intermediate structural products are formed. The net result is an increase in strength and hardness. In irons of suitable composition the tensile strength increase may be about 40 per cent above the original value.

Oil is a commonly used quenching medium. The use of alloys and fairly low total carbon contents are desirable in irons to be heat treated. Because it is nonductile, quenching of gray iron is best confined to simple shapes.

Conversely, for machining purposes, it may be desirable to soften the iron. This is accomplished by annealing. The castings are heated to the temperature range 1500° to 1600° F., and cooled slowly therefrom. Under properly controlled conditions all the combined carbon is converted to graphite. The metal structure then consists wholly of a ferrite matrix and graphite flakes. It is soft (usually around 120-130 Brinell hardness number) and highly machinable. Annealing treatments result in loss of strength, a reduction of about 20 per cent from the original cast strength being usual.

Relief from internal stresses may be accomplished by heating for suitable periods to about 900° F. or slightly above. As a casting cools it contracts, and since cooling rates are not uniform, due to variations in section size, certain portions will contract more rapidly than others. Expansion and contraction effects are also set up by structural changes in the transformation range. These effects set up internal stresses which may seriously weaken castings of complicated design. Although reheating (stress-relief) at about 900° F. does not produce structural changes, the metal does become more plastic, and thus the internal stresses are eliminated

by plastic flow.

Various other heat treatments are used occasionally on gray irons. Among these are flame hardening (surface quenching), isothermal quenching, induction hardening, and nitriding (a case treatment). The principles involved are essentially similar to those employed for steels

PHYSICAL PROPERTIES

The attributes or characteristics which a substance possesses are termed its physical properties.

Density.—The specific gravity of gray irons varies from about 6.95 for weak, coarse grained irons to about 7.35 for irons in the 30,000-40,000 pounds per square inch strength classes. Some of the high strength, low carbon alloyed irons have densities of about 7.5. That of white cast iron is about 7.7. (The specific gravity of cast steel is somewhat higher, about 7.80.)

A specific gravity of 7.7 is about 487 pounds per cubic foot, or 0.29 pound per cubic inch. A specific gravity of 7.0 is about 437 pounds per cubic foot or 0.26 pound per cubic inch.

Gray iron is thus appreciably lighter (per unit volume) than steel. The major reason is the presence of graphite flakes (specific gravity about 2.25) in gray iron.

Melting and Freezing Temperature Ranges.—Unlike pure metals, gray iron does not melt, or freeze, at some single temperature. Each of the structural components: eutectic, primary austenite, and steadite (phosphorus rich component) melts, or conversely, freezes, at a different temperature or temperature range.

The initial freezing point (above which the metal is completely liquid) may be as high as about 2450° F. for low carbon iron. As the carbon (and silicon) content is increased, the initial point (liquidus) becomes lower, reaching, in irons of eutectic composition, about 2100° F.

The final solidification or solidus temperature (or, conversely, the point above which all low phosphorus cast irons start to become liquid) is just above 2100° F.

The phosphorus-rich component steadite remains fluid until a temperature of below 1800° F. is reached.

Specific Heat.—Specific heat is the heat (expressed in Btu. or in calories) required to raise the temperature of a unit mass one degree (° F. in case of Btu., ° C. in case of calories). The specific heat of a high carbon iron at different temperatures is shown in Fig. 9. The specific

FIG. 9. Showing the variation of the specific heat of a high carbon iron with the temperature.

heat increases with increase in temperature. There is an abrupt increase when entering the pearlitic transformation range, where alpha iron (ferrite) changes to gamma iron (austenite). There is a large increase where the metal changes from solid to liquid. The heat of fusion is about 47 calories per gram.

Contraction.—The qualitative relationships of temperature and of contraction characteristics are shown in Fig. 10.

Coefficient of volume shrinkage in liquid state is about 0.006 per cent per degree Fahrenheit (0.011 per degree Centigrade). The volume change during solidification may be as low as 1.6 per cent for a high carbon, high silicon gray iron composition to as high as 5.8 per cent in a low carbon, low silicon white iron composition. The lower carbon gray irons, showing relatively high contraction, liquid to solid, must be well fed with fluid metal if "shrinkage cavity" defects are to be avoided.

The solid contraction of gray iron is lower when graphite content is high, that is, high car-

bon, high silicon irons show lower solid contraction. The solid contraction of a heavy section usually is less than that of a lighter section of similar composition.

Surface Tension.—Surface tension (dynes per square centimeter) in an iron 3.22 per cent carbon, 2.76 per cent silicon and 0.49 per cent phosphorus was found to be 936 at 2313° F., and 914 at 2404° F. (This compares with 1,018 for gold at 2050° F. and 1,178 for copper at 2100° F.).

Thermal Conductivity.—The usual range of thermal conductivity of gray iron extends from 0.100 to 0.140 calorie per square centimeter per second per centimeter per °C.

Thermal conductivity decreases with an increase in temperature and with an increase in flake graphite (accompanied by an increase in total carbon). However, a reduction in combined carbon in a given iron (as by annealing) is effective in increasing thermal conductivity despite an increase in graphite content. (The conductivity of iron carbide is quite low.)

The thermal conductivity of gray iron is lower than that of steel, and markedly lower than that of nonferrous alloys. However, its excellent castability in thin sections (which expose large areas to dissipate heat) and low cost make it suitable for applications such as radiators, stoves, cooking ware, glass molds, drying equipment, and brake drums.

Corrosion.—Gray iron is more resistant than carbon and low alloy steels to many types of corrosion. Although in moist atmospheres it forms a rust coating rather readily, continued rust penetration and consequent disintegration usually is quite slow in comparison to steel, perhaps because the underlying graphite flakes form a protective (and adherent) coating.

In water pipe, cast iron has given splendid life. In soil pipe it usually lasts much longer than steel pipe.

Although different classes of gray iron do not vary much in resistance to a given water or soil condition, different waters and different soils vary quite widely in their corrosive effects. For example, some mine waters contain small percentages of sulphuric acid, others contain copper salts. In these and similar cases specially alloyed metals are required to resist the corrosive effects.

As is the case with all common metals, corrosion resistance of gray iron is impaired when stray electric currents are encountered (as in cities). Many crude oils and refinery products are relatively noncorrosive toward gray iron. High sulphur oils containing moisture, and some of the salt crudes are rather corrosive toward gray iron and steel. Gray irons are usefully resistant to most natural and artificial gases.

Although gray iron is resistant to strong sulphuric acid (60° Bé. to 66° Bé.), it is attacked rapidly by more dilute sulphuric acid. Hot fuming sulphuric acid (oleum) attacks and disintegrates gray iron. Gray iron is fairly resistant to cold concentrated phosphoric and nitric acids, but impurities such as hydrofluoric acid and chlorides materially impair its resistance. Dilute phosphoric and nitric acids attack gray iron quite rapidly. It is not resistant to hydrochloric (muriatic) acid in any concentration.

FIG. 10. Showing qualitatively the contraction and expansion of gray iron at various temperatures.

bon, high silicon irons show lower solid contraction. The solid contraction of a heavy section usually is less than that of a lighter section of similar composition.

The patternmaker usually allows about $\frac{1}{8}$ inch per foot oversize in his patterns to offset the contraction characteristics.

From room temperature to about 850° F. the coefficient of expansion for a given gray iron remains approximately constant. Values usually are in range 6.70 to 6.95×10^{-6} per degree Fahrenheit.

Coefficients for the highly alloyed austenitic irons are much higher, usually from 9.5 to 9.9×10^{-6} per degree Fahrenheit.

Above about 850° F. gray irons often "grow" or expand slowly and permanently due to gradual precipitation of more graphite, and to internal corrosion.

Fluidity.—From a practical viewpoint the term "fluidity of gray iron" is used to indicate the relative ability of the metal to fill a mold, that is, it indicates the running and feeding

Gray iron is resistant to many alkaline and caustic solutions, for example: sodium hydroxide, lye, soda ash, ammonia, etc. It is not embrittled by exposure to strong, hot caustics. Where some slight coloration (due to solution of traces of iron) is not objectionable, gray iron has proved very useful in alkaline fluids, as used in manufacture of glass, sodium silicate, soap, viscose rayon, paper, dyestuffs, textiles, treatment of petroleum, etc. In general, fine close grained irons (as in the 30,000-40,000 pounds per square inch tensile classes) are more resistant to corrosives than are the lower strength, more open grained types.

With but few exceptions, the usage of small amounts of alloy elements is of little or no benefit toward enhancement of the corrosion resistance of gray irons.

Increases in temperature of corrosive fluids usually increase their corrosive effects. Gray irons are frequently used at elevated temperatures. At quite high temperatures (850° to 900° F. and over), ordinary gray irons are subject to "growth," a type of internal disintegration produced by extreme graphitization and considerable internal corrosion. Above about 1100° F. gray irons usually scale rather rapidly, particularly where combustion gases contain corrosives such as oxides of sulphur.

Several types of special cast irons have been developed to resist various types of corrosives. Prominent among these are the austenitic gray irons known commercially as "Ni Resist" and "Causal Metal." These are manufactured to several compositions, embraced within the following range: nickel 14 to 30, copper 4 to 7, chromium 0.5 to 3.5, molybdenum to 1.0 per cent. Some of these are quite usefully resistant to sulphuric acid, over the total range, dilute to concentrated. (They are not resistant to hot oleum.) They are resistant to the less severe types of hydrochloric (muriatic) acid conditions and to some phosphoric acids. Nitric acid attacks them severely. They have fair resistance to some organic acids, such as acetic, oleic, stearic, and red oil. Types containing 18 per cent or more nickel (with or without other alloys) are nearly immune to the corrosive effects of alkalies and caustics, weak or strong. They are, however, subject to stress corrosion in strong, hot caustics. If stresses are kept below about 10,000 pounds per square inch, these types can be used safely with boiling concentrated caustics.

While not immune to rust, these irons form rust slowly and do not disintegrate by rusting. They are resistant to scaling at elevated temperatures and are not subject to growth. In many services austenitic irons are economical substitutes for some of the high alloy stainless steels.

High silicon irons (usually about 15 per cent silicon) are resistant toward many acids, exceptions being hydrofluoric acid and hot concentrated hydrochloric (muriatic) acid. They are useful for conditions where free "wet" chlorine is encountered, and are unusual in that they have good resistance to solutions containing copper salts. The high silicon irons have the disadvantage of being hard and brittle. Thus they are costly to manufacture, and their fragility necessitates that they be handled carefully in installation and usage.

The high chromium irons (usually 24 to 35 per cent chromium) are resistant toward many corrosives, including nitric acids (except fum-

ing) and solutions containing free chlorine. They are nearly rust immune and highly resistant to scaling. They are attacked by strong caustics.

Corrosive conditions vary so widely that specific recommendations should be made only after study of the particular case. This discussion should be used only as a general guide.

Electrical Properties.—Resistance of gray iron to passage of electrical current is higher than that of ordinary carbon steel. Gray iron is not a good current conductor. Increase in flake graphitic content may be expected to increase resistivity. Silicon increase has a similar effect, and so does increase of nickel.

Treatments which produce the nodular form graphite (as in malleable cast iron) tend to decrease resistivity. Commercial gray irons usually have specific resistance (microhms—centimeter) within the range 50-110. Gray iron resistance grids find some uses where fairly high current is involved. Its resistance is relatively high and its thermal dissipation characteristics are good.

Magnetic Properties.—Gray iron (ferrite-pearlite matrix) is magnetic. The highly alloyed austenitic cast irons are but slightly magnetic. Increase in magnetic induction and permeability and decrease in coercive force are attained when the metal is low in combined carbon. Such a material also has low hysteresis loss. An increase in the graphitic carbon content in flake form does not affect the hysteresis loss, but inhibits attainment of high magnetic induction. Lack of structural continuity (because of graphite flakes) causes small demagnetizing forces. This limits retentivity and unsuits the metal for usage in semipermanent magnets. Because of its relatively low permeability and inability to carry as high flux densities as rolled steel, gray iron is of limited use for magnetic applications in electrical machinery. It is used for frame members where flux densities are low, and inexpensive yet complicated shapes are needed.

Mechanical Properties.—The physical properties which concern the mechanical utilization of the material are further classified as mechanical properties. Useful mechanical properties of a material depend largely upon its strength, namely ability to resist forces. Strength may be manifested by resistance to flexure (property of rigidity) and to permanent deformation (property of plasticity). The term "strength" also contemplates resistance to local destruction (as by fracture or breakage) and to more general disintegration (as in wear).

In the case of gray iron the potential strength properties are inherent in the matrix, or continuous structure. The matrix contains many weak graphite flakes. The amount, size, shape, and distribution of these may have a greater influence on strength than the matrix structure itself. Thus, to get a high-strength iron, it is necessary to provide a strong matrix and to control the graphite so that the latter is least effective in breaking up matrix continuity.

Mechanical loadings can be grouped as (1) static (slow rate of loading) and (2) dynamic (rapid or nearly instantaneous loading). Gray irons are particularly useful where static loadings are contemplated. Since they do not possess much ductility and are not appreciably plastic, dynamic loads of high intensity may cause rupture. This does not mean that gray iron is a brittle material. It has quite a useful

range of toughness. Furthermore, it is not sensitive to "notch effects," and also possesses marked "damping" capacity. The latter minimizes the danger of load build-up through synchronous effects, which sometimes adversely affect more ductile metals.

When cast iron is stressed, the resultant strain consists of both elastic and plastic deformation. The true tensile properties of gray iron are not shown fully in the ordinary tensile test. The breaking load or ultimate strength is determined, also the relative rigidity. To determine the possible elastic rigidity and the plastic deformation, repeated loading tests must be employed.

Owing to difficulty in establishing the time elastic modulus in routine testing, this characteristic, in gray irons, usually is expressed as relative modulus at 25 per cent of ultimate tensile strength. This is determined by the slope from 0-0 of a line passing through the strain exhibited at 25 per cent of ultimate tensile strength. Relative moduli of elasticity so determined may be as low as 12,000,000 pounds per square inch for weak soft irons to possibly 28,000,000 for the very highest strength irons whose tensile strengths approach 100,000 pounds per square inch.

Deformation in gray irons has been shown to consist of both elastic and plastic components. It is known that ductile materials such as steel, if loaded for long periods, will fail at stresses much below the tensile strength as determined in short time testing. Test specimens "neck down" and lose maximum total load carrying ability. Cast iron in tension does not neck down or deform much in cross section, even at the breaking load. "Creep tests" are used to determine the maximum loads which can be sustained over long periods of time. In such tests the specimens are loaded to predetermined stress intensities and remain so loaded for long periods of time—about 1,000 hours or more. If continued extension of a specimen is observed, the material is said to creep or flow under the load. If no extension is observed, the material is considered to be within its limiting creep strength.

Such tests indicate that (at room temperatures, and probably up to 650° F. or slightly above) the long-time strength of gray iron approaches the test value determined by the ordinary short-time test, and that yield strength and tensile strength are practically the same, once "set" (permanent deformation) is removed.

Tensile strength is important from the standpoint of engineering design and of manufacturing economy, and it is a variable used in most engineering formulas. It thus influences the size of sections necessary for the required design. With stronger iron, lighter sections often can be used. On the other hand, stronger irons usually are somewhat more expensive to machine and also may require more costly foundry procedures. The designer thus must balance the various economic factors of weight and other production expenses.

Modern practice classifies engineering gray irons according to minimum tensile strength. This classification is given in the accompanying table, an excerpt from the American Society for Testing Materials Specification A-48-41.

As shown, classes from 20,000 to 60,000 pounds per square inch are available under that

Class	Tensile Strength Minimum, pounds per square inch
No. 20.....	20,000
No. 25.....	25,000
No. 30.....	30,000
No. 35.....	35,000
No. 40.....	40,000
No. 50.....	50,000
No. 60.....	60,000

specification. The bulk of commercial gray irons is found in the classes from 25,000 to 50,000 pounds per square inch minimum tensile strength. However, irons above 70,000 pounds per square inch minimum tensile strength are obtainable by special processes, compositions, and treatments. Any iron found testing below 20,000 pounds per square inch tensile strength suggests the likelihood of unsoundness, due to bad design, to improper selection of composition, to poor foundry practice, or to a combination of these.

Usage of gray iron in unfired pressure vessels is restricted to a maximum of 450° F. by various codes. Within this limitation there is no perceptible change in strength; in fact, no published tests have indicated any deterioration up to 700° F., and perhaps appreciably higher in the case of the stronger classes of gray iron. For this reason the American Society for Testing Materials provides a specification (A 278) covering classes suitable for usage to 650° F.

Transverse Strength.—The transverse test is widely used for foundry control and specifications. In this test, the test bar is supported on knife edges and broken by a load applied midway between these supports. The distance between supports is the span. Deflection at the center is measured. Usually the ultimate load in pounds and the ultimate deflection in inches are reported. Since the load and deflection depend on the span and size of the section, as well as the material, the sizes of test bars and span are specified.

The deflection at the moment of breaking gives some measure of ductility. As tested on the conventional transverse bar of 1.2 inches diameter over 18 inches span, deflections on various irons may run from 0.15 to 0.35 inch. The higher strength irons usually show somewhat lower deflections than the soft ferritic irons. High phosphorus lowers deflection values. At a given strength level, higher deflection may indicate tougher iron.

Compression Strength.—Cast iron is much stronger in compression than in tension. On a series of tests covering many types of cast iron the compression strength ranged from 65,000 to 160,000 pounds per square inch. The ratio of compression strength to tensile strength varies from about 4.5-1 for the weaker irons to 2.5-1 for the stronger irons.

Shear Strength.—This property is rather closely proportional to tensile strength. The tensile strength (pounds per square inch) plus 9,000 pounds per square inch approximates the shear strength, in pounds per square inch. (This relationship is for regular gray irons. It would not hold for high phosphorus irons, mottled irons, or chilled irons.)

Torsional Strength.—The ratio of torsional strength (modulus of rupture in torsion) to tensile strength usually is within the range 1.2 to 1.4. The torsional strength is higher than the tensile strength, and increases with increase in

tensile strength.

Hardness.—The Brinell hardness test is a useful one for gray iron castings. The Rockwell test is also used, employing the *B* scale and the steel ball. In the "as cast" condition, commercial (nonalloy) gray iron castings will range from 130-210 Brinell hardness. The alloy cast irons will run higher and heat-treated irons may run over 600 Brinell hardness. Ordinary white irons will range from 321-534 Brinell while alloy white irons may run as high as 700.

Although the trend of indentation hardness is to increase with increase in tensile strength, the ratio of hardness to tensile strength is not constant. One property cannot be safely predicted from the other. The relationship of Brinell hardness to compressive strength is fairly constant. Compressive strength often can be approximated by multiplying Brinell hardness number by 750, up to values of about 200 Brinell hardness number.

Brinell number is a general indicator of machinability, but is not an accurate measure of that property.

Wear.—The term *wear* has generic rather than specific significance. Wear signifies a gradual eating away or dissolution of a structure resulting from the action of mechanically applied agents. Often mechanical wear and deterioration by corrosion act concurrently. The wearing agent may be a fluid (gas or liquid) or a solid.

With a perfect lubricant film there can be no wear. Wear occurs when there is no lubricant, or when the lubricant film breaks down, or when the lubricant is imperfect and a carrier of wearing agents (abrasives).

In the case of metal to metal wear (no lubricant), gray cast iron reveals a high degree of usefulness. Its highly heterogeneous structure effectively inhibits seizure and galling. It not only wears well on itself, but also with many other alloys. It has a tendency to cut much softer alloys, but usually works well with alloys as hard or harder than itself. This property of gray iron is among those responsible for its extensive use in machine tools, where heavy pressures and imperfect lubrication occur, and in automobile cylinders, where temperature and partial lubricant breakdown are factors. An example of metal to metal wear is in automobile brake drums. Gray iron, with its graphitic structure, is more free from the tendency toward seizure than the nongraphitic ferrous alloys.

The properties in gray cast iron which are associated with a low rate of wear are pearlitic matrix, suitable hardness, and high strength. Other things being equal, an iron with a pearlitic matrix will resist wear better than one containing free ferrite.

Heat treatment or special alloy additions which produce martensite and other hard matrices improve wear resistance. Usually some increase in resistance to metal to metal wear may be expected from such increased hardness. The major gain, however, is from increased resistance to abrasive action (sand or grit). Localized heat treatment (flame hardening) has often proved useful.

White cast irons are relatively resistant to abrasion. Some of the alloyed hard white irons not only are resistant to abrasive influences, but also have good resistance to galling and seizure.

Because there are many types of wear, it is

practically impossible to set up any laboratory test which will give an adequate measure of the wear resistance of a material in service. However, laboratory tests have been of value in helping to develop better materials for resisting wear. Some of the conclusions from laboratory tests are as follows: (1) wear resistance increases with matrix hardness; (2) with increasing combined carbon content, the resistance to wear of gray irons increases rapidly up to 0.60 per cent combined carbon and then slightly up to 0.85 per cent; (3) increasing silicon content decreases resistance to wear.

Machinability.—Machinability ranges of cast irons are wide. Cast irons may be made to suit many conditions, remembering that ease in machining is usually inversely proportional to the strength of the casting. Machinability of metals has been variously determined with reference to: (1) tool life, (2) type of finish obtained, (3) power required.

The composition, structure, and physical properties of cast iron extend over a wide range. Dependent upon these factors, cast iron varies from one of the most readily machinable to the most unmachinable of ferrous materials. At one extreme of this range we have completely annealed permanent mold cast iron, which is the most readily machinable; at the other extreme is white or chilled cast iron and iron hardened by heat treatment. Annealed permanent mold cast iron possesses excellent machinability because the structure consists of iron containing no combined carbon and broken up by a high percentage of finely divided free carbon flakes, together with freedom from burned-in sand at the surface. Chilled or white iron is extremely difficult to machine because its structure is composed chiefly of hard iron carbide in both pearlitic and massive form, unbroken by any flakes of free carbon.

When nickel with low silicon and chromium content is used, it permits machining irons of considerably higher hardness than could be machined without the use of nickel. The reason for the ability to machine irons of 225-250 Brinell in alloy compositions is that no massive carbides exist in the matrix. As soon as plain cast iron exceeds a hardness of about 220 Brinell, it usually contains hard carbides, especially at the edges and corners of light castings.

Chromium is a carbide former, and if as much as 0.25 per cent is added to plain cast iron which is already at the limit of machinability, the iron may become difficult to machine. Care should therefore be taken in adding chromium, where machinability is a factor. However, on many soft irons, as much as 0.50 per cent chromium may be added with little effect on machinability.

The high chromium irons (35 per cent chromium), although white irons, structurally are softer and more readily machinable than other white irons.

The austenitic gray irons have approximately the same machinability as regular gray irons of equivalent tensile strength. However, the austenitic irons are subject to surface work hardening when surface distortion without proper metal removal is incurred. Improperly sharpened tools and rubbing action by tools or by chips should be avoided.

The high silicon (15 per cent) cast irons are quite difficult to machine, and grinding is usually employed. The newer carbide tools have

possibilities.

Molybdenum is frequently used as an alloy addition in cast iron to obtain increased strength and wear resistance. Where molybdenum is used to increase hardness and strength without the formation of carbides, machinability will usually be inversely proportional to the hardness and strength produced.

The surface condition of iron castings is most important in determining machinability. Frequently castings are condemned as unmachinable when the metal itself is quite machinable, but difficulty is caused by the presence of burned-in sand on the casting. Where burned-in sand is present, any attempt to make light surface cuts will cause rapid failure of the tool. A sufficient depth of cut must be made to ensure the point of the tool being well below the surface of the casting.

The character of the surface finish obtainable in machining cast iron is dependent upon the size of the graphite flakes and the total amount of the graphite. A high total carbon, high silicon cast iron with large graphite flakes will show a pitted surface when machined due to tearing out of particles of metal between the graphite flakes. Rough cuts taken on coarse grained cast iron will exaggerate the pitted appearance by tearing out small particles of iron. The lower carbon irons will give a much better appearance when machined.

Newer types of tool materials, such as the tungsten carbides and newer machine tool designs permit rates of metal removal in some operations which were not attainable with older tool materials and with older type machine tools. The newer carbide tools are more resistant to the abrasive action of small carbide particles, to the hard phosphorus-rich component steadite, and to burned-in sand. Usually the resistance of cast irons does not produce high tool pressures. It is not prone to seize and crater on tool faces. In many cases newer tools and newer machines permit faster machining of many types of cast iron.

Dynamic Strength.—Metals are often used under rapidly repeated or alternated loadings. To the layman such loadings often are referred to as vibratory stresses. The engineer calls ultimate resistance to such stresses fatigue strength or endurance limit. As with other metals the endurance limit of gray cast iron is less than its ultimate tensile strength.

Deterioration in fatigue is progressive in nature, much more gradual than failure in tension of a ductile material. Under a sufficiently large number of restressings, incipient fractures are started in small flaws, since the latter promote increased localized stress intensity (the start of cracks) and the gradual progress of fracture from these points. In ductile materials, fracture in tension tests is preceded by perceptible elongation and reduction of cross sectional area. In these same materials fatigue may be sudden, as the repetitions of stress result in sudden brittle-acting failure, with no stretch or elongation to give warning of impending fracture, with the exception of possible visible cracks.

It is said (incorrectly) that the steel has crystallized, because of this brittle fracture. It was always crystalline, and the alternating stresses, not the crystallinity of the material, caused the characteristic fracture.

The endurance limit of gray iron in com-

pletely reversed cycles of bending stress varies from about 40 to 55 per cent of its tensile strength. (This is also about the same proportional relationship found in case of steels.) Thus a stronger gray iron can be expected to have a higher endurance limit than a weaker iron. This is also true of alternating torsion stresses and of alternate tension-compression stresses.

Some ductile metals, for example some types of steel, are very sensitive to notches and other surface discontinuities. When these exist, the material may fail in fatigue (endurance) at quite low stresses. Fortunately many gray irons, especially the lower strength classes are much less affected by notches and other surface discontinuities.

As is the case with most metals, corrosive effects may lower the endurance limits of gray irons.

The effects of elevated temperature are quite similar on both tensile strength and endurance limits. Up to about 800° F. these properties are changed little from their room temperature values.

Damping: Gray iron is effective in damping or absorbing vibratory impulses. This property (damping) is measured by the length of time it takes for a vibrational impulse to die out. A hard steel tuning fork has low damping capacity. If struck it will continue to vibrate audibly for some seconds, and inaudibly for some longer time. If the fork were made of lead, it would sound dead when struck. Lead has very high damping capacity. Gray iron is intermediate in this characteristic. Imposed oscillations are more rapidly dampened in cast iron than in steel.

Damping capacity is a significant factor in choice of materials for machines which encounter vibrational impulses during operation. If such impulses synchronize, the amplitude of vibration may become very great, and result in failure or breakage. In all cases vibrations mean loss of useful power, and interfere with accuracy in alignments. Designers have learned to take good advantage of gray iron's relatively good damping capacity.

Impact: Gray iron is not employed where high resistance to impact or shock is a requirement. It does, however, possess a surprisingly wide range of usefulness where mild shock resistance is required. Automotive pistons are a familiar example. Lately, even in large Diesel engines, gray iron crankshafts have proved quite adequate.

There is no exact relationship between shock resistance and tensile strength. Stronger irons, particularly the lower carbon varieties, usually are the more shock resistant. Of two irons alike in strength, the one with more ductility, or with greater deflection in the transverse test may be expected to have the greater shock or impact resistance. High phosphorus content tends to lower shock resistance.

JOHN W. BOLTON,
The Lunkemheimer Co.

4. PIG IRON.—Pig iron is the crude, commercial, metallic product of an iron blast furnace, and is the basis of the whole iron and steel industry. Practically all forms of iron and steel products in existence originally came from pig iron, which in turn was smelted from natural iron ores or from iron-bearing byproducts; meteoric iron (usually museum exhibits) and "direct reduction" iron, often in the form of

powdered iron and Swedish sponge iron, are the commercial exceptions, but in very small tonnages. The name "pig iron" was applied first to solid pig iron because it was cast in a sand pig bed where the molten iron ran through a long groove or trough and thence into many smaller grooves at right angles, so that it looked like a litter of pigs nursing at the side of the mother sow. When the iron solidified, the long piece became the "sow" and the offshoots became the "pigs" that had been molded in the sand "pig bed." When cast iron molds, or "chill beds," replaced the sand pig bed (which had to be made up after each cast), the names sow and pigs followed the solid pig iron. When the iron from the furnace was poured into a pig machine, there were no longer any sows and all the pig iron became "iron in pigs." Pig beds are becoming obsolete, but pig iron is the commercial and technical name given to this important metal whether it is in its liquid or in its solid form. Iron in pigs is the name given by the United States Tariff Commission to solid pig iron; "hot metal," or "direct metal" is the name given by iron and steel men to the molten metal as it is conveyed from the blast furnace to the steel mill or to the foundry for "direct castings."

Contrary to the decision once announced by the United States Tariff Commission, "that molten iron is not an article of commerce," much molten iron is carried on standard railroads, over rivers, between different towns and companies, as well as between various departments of the same steel company. Metallurgically there is no reason why hot metal could not be transported across the boundary lines of adjoining countries, such as across the St. Mary's River from the Canadian "Soo," or across the Rio Grande at Piedras Negras, Texas, into Mexico. Hot metal is delivered directly from "merchant" blast furnaces to large foundries, making such heavy castings as ingot molds or cast iron pipe.

A "merchant" blast furnace is one that makes pig iron for foundries and sells it on the open market; a "steel plant" or "captive" blast furnace produces steel-making pig iron, usually basic or Bessemer iron.

Where smaller castings are made in large quantities, like engine blocks for automobiles, it is sometimes the practice to pour the hot metal from the blast furnace into a hot metal mixer. Usually molten scrap (cast iron and steel) from a cupola is mixed with the hot metal from the mixer, and the two streams of molten metal flow into a receiver that is continually kept at the right temperature for pouring into the molds. The analysis of the molten metal in the receiver is controlled by mixing the right amounts of hot metal from the mixer and from the cupola.

There are many grades of pig iron classified chiefly by the chemical analysis, especially the phosphorus content, partly by the subsequent use, and also by the blast furnace fuel used in its production. The General Technical Committee of the American Iron and Steel Institute has selected 14 grades of pig iron listed below as representing compositions of proven merit and in extensive use for a wide variety of purposes. Such irons are called standard grades of pig iron.

It is recognized that compositions other than those listed in the tables of irons may be produced and will at times be required for specialized uses. Irons so specified are termed

nonstandard irons.

For convenient reference, standard grades of pig iron listed herein are designated by the use of prefix letters, suffix letters, and numerals. A prefix letter is used which designates grades in order of increasing phosphorus content, as follows:

Designation	Phosphorus content
LP Low-phosphorus	0.035 per cent, maximum
LPi Intermediate low-phosphorus	0.036 to 0.075 per cent
Bes Bessemer	0.076 to 0.100 per cent
M Malleable	0.101 to 0.300 per cent
B Basic—Northern	0.400 per cent, maximum
F1 Foundry—Northern low-phosphorus	0.300 to 0.500 per cent
Fh Foundry—Northern high-phosphorus	0.501 to 0.700 per cent
Fs Foundry—Southern	0.700 to 0.900 per cent
Bs Basic—Southern	0.700 to 0.900 per cent
Cn Charcoal iron—Northern	0.100 to 0.200 per cent
C1 Charcoal iron—Southern	0.035 per cent, maximum
C2 Charcoal iron—Southern	0.100 to 0.200 per cent
C3 Charcoal iron—Southern	0.400 to 0.700 per cent
S Silvery	0.300 per cent, maximum

Silicon and manganese contents are designated by a six-number system in which the first three numerals designate the average silicon content; the average manganese content is similarly indicated by the last three numerals. For example, in LP 113088, LP denotes phosphorus content of 0.035 maximum; 113 denotes silicon content of 1.00 to 1.25 per cent; and 088 denotes manganese content of 0.76 to 1.00 per cent.

The four preceding paragraphs are quoted from pages 3 and 4 of Section 1 of *Steel Products Manual Pig Iron and Ferroalloys*; then there follow 31 pages, with 15 tables of the intricate variations of pig iron that can be made in a blast furnace, having different combinations of the four chief elements, silicon, sulphur, phosphorus, and manganese. The ferroalloys commonly made in a blast furnace are spiegeleisen, ferromanganese, ferrosilicon, and ferrophosphorus. Other ferroalloys with commercial grades are ferrosilicon, silicomanganese, ferrochromium, ferrovanadium, ferrotungsten, ferromolybdenum, and ferrotitanium.

All of the above pig irons, made with coke, are sold and graded on chemical analysis; grading and selling by "fracture" is obsolete. Charcoal pig iron was sold and graded on "fracture" for the past 300 years in the United States, but now there are no more charcoal blast furnaces in the latter country that make sand-cast pig iron; the only charcoal blast furnace left uses a pig casting machine and the iron is sold on analysis. This makes obsolete the 15 grades of charcoal pig iron that prevailed up to World War II.

The market price of charcoal pig iron has always been higher than that of any other grade, beginning with quotations of anthracite and charcoal pig iron in Philadelphia in May 1842. (For about 200 years previously there had been nothing but charcoal pig iron made in this country; in 1946, only coke pig iron and charcoal pig iron were made.) The premium on charcoal pig iron for about 20 years previous to World War II averaged \$7 per ton above similar grades of coke pig iron; this premium was doubled during the war, owing to the scarcity of charcoal pig iron.

Actual market prices of pig iron will not be given here; they can be found in such trade journals as *The Iron Age* and *Steel*. There are silicon differentials, not to exceed 50 cents per ton for each 0.25 per cent silicon content above

the base grade, which is 1.75-2.25 per cent.

In some iron ores, especially those imported from the shores and islands of the Mediterranean, there are small amounts of metals that give trouble in smelting, such as zinc, lead, and arsenic; the zinc and lead do not go into the pig iron, but arsenic does and gives trouble in the subsequent steel. Small amounts of vanadium, nickel, and copper in the iron ores go into the pig iron with beneficial results.

Blast Furnace.—The iron blast furnace (see illus.) is the largest of metallurgical furnaces. In principle, it is one of the simplest means of separating a metal from its oxides and producing a commercial product. In practice, it is a complicated apparatus for handling large tonnages of solid materials, tremendous volumes of cold and hot atmospheric air and still larger volumes of hot gases, for furnishing the room in which a multiplicity of chemical reactions and physical changes can take place at the same time, and for providing a hearth, or crucible, where the molten metallic and nonmetallic products can be received, separated and drawn off, separately, at stated intervals. The blast furnace itself is a vertical series of steel-clad cylinders lined with refractories, through which a continual flow of solids is descending from top to bottom, meeting a continual flow of hot gases ascending from bottom to top, and then outside. Down through this gigantic heat exchanger, which sometimes is 105 feet high from the iron notch to the top, passes a column of several thousand tons of ore, coke, and limestone in 24 hours, all of which is gasified or liquefied by the time it reaches the hearth of the furnace. Up this vertical furnace is blown a hurricane of hot gas that began with 60,000 to 90,000 cubic feet of atmospheric air per minute. Here is one of the paradoxes of blast furnace practice. A big modern blast furnace has a cubical capacity of 35,000 to 45,000 cubic feet; in operation, it is filled up to the stock line with solid iron ore, coke and limestone, and yet a volume of air blast equal to twice its cubical contents is blown into it every minute. Thus there is a descending column of cold solids, getting hotter every minute, meeting an ascending column of hot gases, getting cooler every minute. In addition to the physical phenomena of the exchange of heat, the working of gravity, the calcining of limestone, the roasting of ore, and the diffusion of gases, there are chemical actions and reactions of reduction, oxidation, solution, carbon impregnation, slag formation, sulphur absorption and sulphur removal, and, incidentally and only for a short interval, the formation of the sponge iron which quickly absorbs carbon and becomes the more fusible pig iron, the final product of the iron blast furnace.

Previous to World War I there was no rule for determining the capacity of an iron blast furnace, and 600 tons of pig iron per 24 hours was about the maximum production. In October 1920, the Southern Ohio Pig Iron & Coke Association, after two years of work by a special committee, announced a rule for calculating the capacity of a blast furnace, as follows: "Regardless of grade of pig iron produced, blast furnaces of modern construction should burn about the same amount of fuel daily under same operating conditions. For each grade of pig iron the tonnage which can be produced will depend upon the quality of fuel used, yield of ore mixture

and blast temperature. The tonnage of coke which can be burned in a unit of time has a certain ratio to the working volume of the furnace. The working volume is taken as volume from center line of tuyeres to two feet below bell when closed . . . It has been found that, with good practice, 60 pounds of coke can be burnt each 24 hours per cubic foot working volume . . . It is necessary to adopt a base coke, a base theoretical yield ore mixture, and a base hot blast temperature and then make allowances for variations as encountered."

The analysis of the base coke referred to is as follows:

	Per cent
Fixed carbon	89
Sulphur	1 (maximum)
Ash	9 to 10
Volatile	1 to 2

The structure of the coke is tough, but not dense or fragile, and free from breeze.

By the year 1930 the output of a standard sized blast furnace was 1,000 tons of pig iron per 24 hours; during World War II, it was 1,500 tons, with a few actually making 1,700 tons at times, with a maximum for a day of 1,976 tons.

The main parts of a blast furnace are: (1) the hearth or crucible where the molten iron and slag collect; (2) the tuyere zone where the air blast enters and combustion takes place; (3) the bosh or zone of fusion; (4) the shaft with its upper and lower zones of reduction and its exchange of heat from ascending hot gases to the descending column of solid raw materials; (5) and the top with its receiving hopper, double bells and hoppers, revolving top, downcomer arches for the escaping gases, and uptakes and bleeders to relieve any sudden extra gas pressure inside the furnace. In order to get the optimum results as to tonnage, all of these parts must have the proper dimensions, angles, and locations. These are called the lines of the furnace.

All these sections of the furnace are encased in steel plates, of strength and thickness requisite for the demands of the expansion from heat and pressures inside the furnace. Each section is lined with firebrick and other refractories, suitable for the demands of that section, such as: excessive temperatures and the chemical and physical action of large quantities of molten iron and slag in the hearth; intense heat and evolution of hot gases in the bosh; the wear of the slowly descending solid materials and the abrasive action of the rapidly ascending, dust-laden, hot gases in the shaft; and the wear from impact of the cold raw materials that are dropped off the big charging bell at the top of the furnace, and where there is danger from the chemical, as well as the physical, action of the swiftly moving hot gases. In order to protect these several kinds of refractory linings, and to extend the life of the whole lining of the furnace, many devices are used, mostly hollow water-cooled iron, or copper, plates or castings. Naturally, the hearth needs the greatest protection, because at times it will contain several hundred tons of molten iron, and slag, at maximum temperatures of slag approximately 2800° F.

Besides using the highest grade of firebrick, burned at high temperatures in the brick kiln and machine-ground to exact size, sometimes in the larger furnaces a layer of sillimanite is spread

across the hearth between the courses of the bottom blocks (firebrick 18" by 9" by 6"). Between the firebrick solid bottom, the firebrick side walls, and the heavy steel hearth jacket, there are placed cast iron, water-cooled, vertical hearth plates extending the total height of the jacket. At the tuyere zone there are the copper water-cooled tuyere coolers and also many copper (generally called "bronze") bosh plates above, below and between the tuyere coolers. The bosh walls are protected on the outside by heavy steel bosh bands, or else enclosed entirely by a steel bosh jacket; in either case there are several rows of copper ("bronze") bosh plates, through which flows a constant stream of water. The shaft of the furnace, extending from the mantle to the top platform, has a steel shell outside the brick lining. Between the brick and the steel there is usually some packing that acts as insulation and also as an expansion joint. The brick lining of the shaft, mostly of inwall brick, is sometimes protected by cooling plates of either copper or of water-cooled cast iron plates. The firebrick at the top of the furnace consists of very hard, dense brick, generally protected at the stock line, and for several feet below, by some sort of armor, either of steel or cast iron.

The waste gas ("top gas," or blast furnace gas) from the top of the furnace, amounting in volume as it passes out of the furnace to about 30 per cent more than the volume of atmospheric air blown into the furnace, goes through one or more downcomers extending downward from the top of the furnace to the dustcatcher, where the heavier particles of the flue dust are removed from the hot (250°-450° F.) dry gas, and thence to some form of gas washer, scrubbers and dryers. The final gas is cleaner than the air we breathe, the dust being reduced from about 10 grains per cubic foot down to less than 0.01 grain of dust per cubic foot.

The cleaned blast furnace gas of about 90-105 Btu. per cubic foot is used for heating the hot blast stoves (20 to 25 per cent) under boilers, underfiring of coke ovens, in gas engines, and sometimes at integrated steel plants it takes the place of producer gas for soaking pits, and reheating furnaces.

Hot Blast Stoves.—The air blast from the blowing engines is heated to a temperature as high as 1600° to 1800° F. in a regenerative hot blast stove made of firebrick checkerwork incased in steel sheets 20 to 25 feet in diameter and 85 to 105 feet high, in which the cleaned waste gas from the furnace has been burning for two hours or more. There must be the right balance of heating surface and brick volume so that the heat from combustion of the gas can be stored up and then given out again to the air blast which flows through the checkerwork in the opposite direction from the hot gas. Usually two, or more, stoves are being heated while one or two stoves are "on the furnace." A three-pass stove will have its individual stack, as seen in the photograph; two-pass stoves have one large draft stack in common.

Hot Metal Ladles.—The hot metal ladles mentioned above are of two general types. One is the upright, short-pour ladle car of 50 to 100 tons capacity on a heavy, underslung, steel frame mounted on two standard railroad trucks. A motor for tilting the ladle is mounted on the frame. The other is the Pollock mixer-type, hot metal ladle car of 100 to 200 tons capacity, as

shown in the accompanying illustration, which can be completely enclosed for safe transportation over standard railroad tracks for considerable distances. Both types of ladles are lined with special ladle brick or with silica "firestone."

Hot Metal Mixers.—At steel plants and at large foundries, the hot metal from successive casts of one or more blast furnaces is poured from the hot metal ladles into a hot metal mixer which is a big, steel enclosed container mounted on trunnions, with a thick firebrick lining, kept hot by a gas or oil flame, and tilted for pouring into the transfer ladles with the same big hook and overhead crane as is used for handling the hot metal ladles. The large, mixer-type, hot metal ladles can be poured directly into the transfer ladles that are used to fill the open hearth steel-making furnaces.

Blast Furnace Practice.—The efficiency of the modern iron blast furnace depends on the time and the regularity of the "through-put" of the raw materials that are charged into the top of the furnace through the revolving top and through the double bell and hopper, and down into the furnace itself. The revolving top distributes the materials regularly onto the "big bell" which is a conical, steel casting suspended by a bell rod connected to the bell beam in such a way that the bell travels vertically downward to deliver the stock (ore, coke, limestone, and scrap) into the furnace, and then travels upward to seat itself tightly on the beveled edge of the big hopper so as to prevent the escape of the blast furnace gas. The little bell is then lowered so that the stock in the little hopper drops onto the big bell. The little bell and hopper are revolved by a mechanism that causes the delivery of the stock onto the big bell in such a predetermined way that the "charges" are delivered evenly around the periphery of the stock line, first a charge of coke and then a charge of ore and limestone, and any scrap that is charged into the furnace. This device is the McKee revolving top. During World War II, these big charging bells reached enormous sizes, some being 1½ feet in diameter and weighing 45,000 pounds.

The raw materials are taken from the ground level to the top of the furnace in the skip cars running on the tracks of a double skip hoist, generally electrically operated, as shown in the photograph. The coke is filled into the skip cars from the coke bins without weighing; all ores and limestone are carefully weighed in a scale car before being dumped into the skip cars.

It is the responsibility of the blast furnace superintendent to see that just the right volume of coke is charged into the furnace during the right intervals of time, that the right weights of iron ore and of limestone follow each charge of coke, and that the right volume of air blast is heated to the right temperature and blown regularly each minute into the furnace at the tuyeres at the right blast pressures.

Because the blast furnacemen of the United States, operating men, executives and engineers, had developed during the period between the two world wars a blast furnace practice that accomplished wonderful results as to big tonnages and operating economies, there grew up what is called "American blast furnace practice." The American designs of blast furnace plants, and the methods for their operation have been spread all over the world, so that by the end of World

War II the big 1,500-1,700 ton furnaces were making pig iron in Russia and India and other countries as well as in the United States. Much of this progress was due to the free exchange of

per cent; Al_2O_3 , 3.45 per cent; CaO , 17.38 per cent; MgO , 0.56 per cent in the dried sample. The natural ores and minerals of iron are as follows:

Name	Classification	Formula	Fe content (per cent)	Sometimes called
Hematite	Ferric oxide (hexagonal)	Fe_2O_3	70.0	Red ore
Magnetite	Magnetic oxide (octahedral)	Fe_3O_4	72.4	Black oxide
Martite	Ferric oxide	Fe_2O_3	70.0	Brown ore
Limonite	Hydroxide	$2\text{Fe}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$	59.8	
Turgite	Hydroxide	$2\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$	66.2	
Goethite	Hydroxide	$\text{Fe}_2\text{O}_3 \cdot \text{H}_2\text{O}$	62.9	
Siderite	Carbonate	FeCO_3	48.2	
Franklinite	Oxides	$(\text{Fe, Mn, Zn})\text{O} \cdot (\text{Fe, Mn})_2\text{O}_3$	21.0	Spathic iron Franklin ore
Ilmenite	Oxides	$(\text{FeTi})_2\text{O}_3$	variable	Titaniferous magnetite
Chromite	Oxides	FeCrO_3	variable	Black sands
Wolframite	Oxides	$(\text{FeO, MnO})\text{WO}_3$	variable	Iron pyrites
Pyrite	Sulphide	FeS_2	46.7	
Pyrrhotite	Sulphide	FeS_7	variable	Magnetic pyrites
Chalcopyrite	Copper-iron sulphide	CuFeS_2	30.4	Copper pyrites
Marcasite	Sulphide	FeS_2	46.7	White iron pyrites

ideas and experiences of the operating men in such groups as the Southern Ohio Pig Iron & Coke Association (now defunct), The Eastern States Blast Furnace and Coke Oven Association, the Blast Furnace and Coke Association of the Chicago District, and the Iron and Steel Division of the American Institute of Mining and Metallurgical Engineers.

Raw Materials.—The essential raw materials for the production of pig iron are iron ore, fuel, flux, and the air blast. A few places in the world have all these in close proximity, notably the Birmingham District of Alabama. Usually, one or more ingredients are transported long distances by rail and water, as in the case of the Lake Superior iron ores which go hundreds of miles to the blast furnaces using the famous Pittsburgh seam of coal for their coke. The assembling costs of the raw materials is a vital factor in the cost of the pig iron.

Iron Ores.—The iron ores commonly used in the iron blast furnace are the oxides of iron: ferric (Fe_2O_3) and magnetic (Fe_3O_4). These are more abundant than any other iron-bearing minerals. The ferric oxide, usually called hematite, often occurs in various forms of hydrates, or combinations of Fe_2O_3 with fixed proportions of "combined water" (H_2O). The Brown Ores of the South and the Southwest, especially in Alabama and East Texas, are hydrated oxides of iron. The percentage of iron (Fe) that must be in an iron-bearing mineral before it can be classed as a merchantable iron ore varies greatly from 25 per cent to 70 per cent, depending on its capability of being beneficiated before charging into the blast furnace, and on the character of the "gangue" of the iron mineral, that is, the nonmetallic elements that are combined with the iron either chemically or mechanically. The gangue of some iron ores, especially certain ores in Red Mountain, in the Birmingham District of Alabama, contain enough lime and magnesia to flux all the silica and alumina in the gangue of that ore, and even a little left over to flux a part of the ash in the coke. These are called "self-fluxing" ores, and, although the iron content is low, they are very desirable. The ore from Muscoda No. 4 mine is such an ore, with the following analysis: Fe, 35.57 per cent; SiO_2 , 12.38

The iron ores that are compounded with other metals, especially the sulphide ores, must be treated in some way to separate the iron as far as possible from the other ingredients, usually by roasting, before they can be charged into the blast furnace. Besides the natural iron ores mentioned above, there are several iron-bearing byproducts containing enough iron to make it profitable to smelt them in the iron blast furnace. These are:

(1) Blue Billy, the iron oxide residue from roasting sulphide ores; (2) flute dust, the fine dust carried out of the top of the blast furnace, and recovered in the gas cleaning equipment; (3) roll scale, the rich iron oxide obtained while rolling steel in the steel mills; (4) mill cinder, the rich iron slag from the puddling process for making wrought iron; (5) slag, from the open hearth furnaces, Bessemer converters and Spiegel furnaces; (6) borings, turnings, crop ends, stove plate, slag scrap, miscellaneous small iron and steel scrap.

An integrated steel plants (an integrated steel plant includes byproduct coke ovens, blast furnaces, open hearth furnaces or Bessemer converters, and rolling mills) it is usual to send a part, or all, of the open hearth slag to the blast furnaces so as to utilize the fluxing value of the excess lime and magnesia and recover most of the manganese and iron. An ordinary open hearth slag will have 10-16 per cent Fe; 4-7 per cent Mn; 43-48 per cent CaO ; 6-8 per cent MgO ; 12-20 per cent SiO_2 ; 2-8 per cent Al_2O_3 ; 1.50-2.35 per cent P; 0.16-0.22 per cent S. Open hearth furnaces producing ingot iron make a slag much higher in iron and lower in lime. The slag from blast furnaces making spiegel contains enough manganese (about 12 per cent) to make it desirable to smelt with iron ores that are deficient in manganese, such as the Eastern magnetites.

Fuels.—Practically all the pig iron in the world is made with coke, either beehive coke or byproduct coke. The only other fuel in the United States is charcoal. Even in the electric furnace process for making pig iron, solid fuel of either coke or charcoal must be used. Charcoal is the blast furnace fuel used in Brazil. It was the only fuel used in the United States for the first 200 years, up to the use of anthra-

cite in 1840. Anthracite predominated from 1855 to 1875; beehive coke from 1875 to 1919; and byproduct coke from 1919 on. The peak tonnage of charcoal pig iron in the United States was reached in 1890 (628,145 gross tons), with 135 active charcoal blast furnaces, and the production has steadily decreased ever since, with only one charcoal furnace in blast at the end of World War II, and one being built. Anthracite ceased to be a regular blast furnace fuel during World War I. It has been used intermittently, mixed with coke, during coke shortages. It is being used in Italy and Russia. Small amounts of certain kinds of bituminous coals (No. 1 Sharon seam in Ohio) that are noncoking are still used for certain special grades of pig iron, mixed with coke, in the United States, and in Scotland.

In the manufacture of beehive coke from bituminous coking coals, all of the volatile by-products are wasted in the black smoke that arises from the beehive ovens that predominated in the coke industry up to World War I and became almost extinct just previous to World War II. The demand for coke then became so great that many new beehive coke ovens were built in many parts of the country where coking coals were available. Since a part of the coal itself is burned to furnish the heat for the coking process, the yield of coke in the beehive oven is only 62 to 66 per cent, depending on the amount of volatile matter in the coal.

Byproduct coke was first used in the chemical industry where a dense lumpy coke was desired and where the byproducts required complicated chemical processes and costly equipment. The introduction of byproduct coke as a blast furnace fuel proceeded rather slowly, but when prejudice and inexperience were overcome by hearty cooperation of the coke oven men and the blast furnacemen, the great advantage of conserving the volatiles so as to reduce the cost of the coke was recognized, and byproduct coke became the almost universal blast furnace fuel wherever coking coals were available.

The yield of coke in byproduct coke ovens is considerably higher than in beehive ovens, but it is still dependent on the percentages of ash and volatile matter in the coal. A good coal would yield about 1,400 pounds of coke per ton (2,000 pounds) of coal; 100 pounds of coke breeze; 10 gallons of coal tar; 2.8 gallons of motor benzol; 24 pounds of ammonium sulphate; 6,500 cubic feet surplus gas. A good blast furnace coke has about 2 per cent moisture; 89 to 92 per cent fixed carbon; 1.50 to 2.00 per cent volatile matter; 4.50 to 7.00 per cent ash; and not over 0.60 per cent sulphur; coke with over 1.0 per cent sulphur is not standard and is usually subject to a reduction in price. All byproduct coke is screened and sized, the smaller sizes being sold for domestic coke; the size for blast furnace coke varies according to conditions of the supply and the vagaries of blast furnace operators; usually it is coke that passes through screens having openings or mesh 4 inches to 3 inches and remains on screens of 1½ inches to 1 inch mesh. Blast furnace coke should be tough, not dense or fragile, and free from breeze.

Flux.—The smelting of iron ores requires a flux stone, either an almost pure limestone (calcium carbonate, CaCO_3) or a dolomite—a double carbonate of calcium and magnesium (Ca,Mg) CO_3 . Lime (CaO) is essential for the forma-

tion of CaS , calcium sulphide, the very stable compound which removes the sulphur that otherwise would combine with the iron and make an undesirable high-sulphur pig iron. Some magnesia (MgO) is always desirable in a flux stone as it tends to lower the melting temperature of very basic slags. Too much magnesia simply increases the bulk of slag beyond the optimum volume. The ash of the blast furnace fuel and the gangue of the iron ores (the earthy ingredients of the blast furnace "burden") combine with the lime and magnesia and go into the slag. The decrease of efficiency of the fluxing value of the stone will be approximately double the amount of silica and alumina contained in the flux stone.

Slag.—The control of the composition of the slag is of prime importance to the blast furnace superintendent, because the smooth running of the furnace and the quality of the pig iron depend upon it. The temperature of the molten slag (above 2700°F . in making basic iron), which is always higher than that of the molten pig iron (2450° to 2700°), determines the critical temperature of the hearth above which only certain necessary operations of the process can be carried out. (J. E. Johnson, Jr., "The Physical Action of the Blast Furnace," *Transactions, American Institute of Mining and Metallurgical Engineers*, vol. 36, p. 472, 1906.)

The character of the slag is the determining factor in the "personality" of the pig iron, especially as to the controllable limits of silicon, sulphur, and to a certain extent the manganese; it also controls the proportions of combined and graphitic carbons in the pig iron, but not the total carbon.

There are various methods for slag disposal, such as running molten slag direct to dry slag pits alongside the blast furnace, direct to a granulating pit, filled with water, alongside the furnace. It may also run directly into cinder ladles ("slag pots") which are hauled away by a locomotive to dry slag pits at a distance from the furnace, or furnaces, or used for fills along a river bank or in low land. (See article 5, "Wrought Iron" for another use of molten slag.) Several types of cinder ladles are shown in the illustration alongside the cast house wall.

The uses of slag have been increasing greatly since the days when unsightly "slag dumps" were seen near every blast furnace of the 19th century. These dumps are now being reclaimed for making fireproof aggregate, roofing material, or mineral wool. Granulated slag is used for making portland cement by grinding to a slurry, mixing with limestone, and burning in a rotary cement kiln; it is also used for insulating packing, railroad fills, and "making ground" in low lands. Air-dried, solid slag is crushed, screened to different sizes, and sold for making roads, railroad ballast, concrete, and roofing material. Mineral wool is made direct by blowing a jet of steam into the molten slag as it runs from the furnace, or after the solid slag has been melted, in an ordinary cupola with coke. Such mineral wool is so white that it is called "slag wool," and is made into "bats," or pads, and used for insulating in buildings and refrigerators. "Loose wool" is the slag wool in small balls about the size of marbles that can be blown by compressed air inside the walls and roofs of dwellings to insulate them from cold and from hot weather.

In some cities the building code specifies

blast furnace slag as aggregate for reinforced concrete above certain heights; limestone aggregate cannot stand the heat like the slag.

Air Blast.—Of all the materials used in the blast furnace for making a ton of pig iron, the weight of the atmospheric air blown in through the tuyeres for the combustion of the coke is the greatest, as is shown by the following table:

Iron ore—52 per cent Fe.	4,047 lbs.—1,807 gross tons
Coke—8 per cent ash....	1,900 lbs.—0.848 gross tons
Limestone—3 per cent SiO ₂	1,000 lbs.—0.446 gross tons
Solid materials	6,947 lbs.—3.101 gross tons
Air blast	7,942 lbs.—3.545 gross tons
Total materials	14,889 lbs.—6.646 gross tons

Totals per 2,240 pounds pig iron

Generally the air blast comes directly from the atmosphere outside the blowing engine house through pipes to the hoods over the intake valves of the air cylinders of the blowing engines, which may be vertical or horizontal reciprocating engines driven by steam, gas, or electricity. Again, they may be turbo blowers of up to 90,000 cubic feet of air per minute and up to 30 pounds pressure. As far back as the end of the 18th century, the British ironmasters were trying to improve the quality of the air blast when they discovered that their blast furnaces did not make as much pig iron in the hot summer months as in the colder winter months. They overlooked the fact that it is the *weight* of oxygen in the air blast that controls the weight of fuel burned at the tuyeres of the blast furnace, and that the hot air of the summer weighed less per cubic foot than the cooler air in the winter months. Paradoxically, and with due respect to those early researchers, the greatest tonnage of pig iron yet made in a day, a week, and a month was by No. 2 Edgar Thomson blast furnace at Braddock, Pa., in the month of July 1945 (1,976 tons, 12,189 tons, and 50,590 net tons respectively). At the end of another century, James Gayley and David Baker, brilliant and courageous blast furnacemen, experimented on the reduction of the moisture in the air blast. Gayley went so far as to freeze out all the moisture possible by refrigeration with ammonia machines, and patented and operated the Gayley dry-blast process which startled the steel industry with its amazing economies and big tonnages. As blast furnace practice was studied more and more by technical men, it was found that a certain amount of moisture in the blast was essential for the optimum catalytic action of the hydrogen that was dissociated in the tuyere zone. Therefore, there must be a certain amount of moisture in the air blast at all times, and if this certain amount (not less than about three grains of moisture per cubic foot of blast) can be kept constant by air conditioning apparatus, then there will be more regular operation of the furnace and a lower amount of coke per ton of pig iron.

The enriching of the percentage of oxygen in the air blast by removing a part of the nitrogen or by adding oxygen has not yet become standard practice, because no one has yet demonstrated that it would make more or cheaper pig iron. The inert nitrogen of the atmospheric air blast acts as the carrier of the surplus heat of the hearth upward through the descending column of solids which must be brought from the outdoor temperature to the white heat in front of the tuyeres. However, it is not only possible,

but most probable, that a reasonable increase in the percentage of oxygen in the air blast would help to give a higher blast temperature, a lower coke consumption per ton of pig, and increased tonnage, all of which would be debited by the cost of producing the impure oxygen.

Beneficiation of the Raw Materials.—Very few, if any, of the iron ores are charged into the blast furnace just as they come from the mine. Some of the preparation, or beneficiation, may be simply the screening out and crushing of the lumps so as to have the ore more nearly all of the same screen size. In some cases the beneficiation is very elaborate, including crushing, fine grinding, magnetic concentration, tabling, flotation, and sintering. In cases of excessive moisture, iron ores are put through dryers to remove some of the excess water, thus increasing the iron content and decreasing the freight to destination. Iron carbonate ores are roasted, either in rotary or stationary kilns, for removal of most of the carbonic acid gas and making the ore into the richer hematite. Some carbonate ores contain enough iron sulphide so that the ore can be crushed fine and the sulphur used for fuel in a sintering machine. The abundant magnetic iron ores of New York, New Jersey, and Pennsylvania, some of them running as low as 30 per cent in iron, are crushed and ground fine and put through magnetic concentrators that remove most of the gangue and produce a rich magnetic iron ore that is too fine to be put into a blast furnace and must be agglomerated in a sintering machine. It has been found that the famous red ores of Alabama will have to be crushed to smaller sizes than was customary when both the ore and the coke were very cheap in the Birmingham District. In crushing and screening the red ore, much fines are produced and these must be sintered before charging into the blast furnace. Some fine ores are nodulized in a rotary kiln, and some few are biquetted, but sinter gives the best results in the blast furnace. The washing of iron ores which are mixed with clay and sand removes this worthless material and in some cases also removes excess moisture. This is done in "log washers."

Sintering Plant.—Here shown is the exterior of one of the largest of the new sintering plants erected by the United States government during World War II, from a photograph of the Greenawalt sintering plant at Tahawus, N. Y., built for, and operated by, the National Lead Company. The estimated annual capacity is 630,000 net tons of sintered magnetic iron concentrates from the titaniferous iron ore of the famous MacIntyre mine at Sanford Lake; the ilmenite (oxide of titanium) is first removed from the ore. This plant is dust-proof.

Statistics.—The production of pig iron in the United States began in the little charcoal blast furnace in Saugus, Mass., built in 1645. Nothing but charcoal pig iron was made in the United States until 1840 when anthracite was first used. James M. Swank, in his classic, *The Manufacture of Iron in All Ages* (1892), says, "No tabulated statistics of the production of iron in our Colonial history are extant, and the materials for such a compilation appear to be entirely wanting." The census report of 1810 shows 153 blast furnaces and a production of 53,908 tons of cast iron. A chart showing the annual pig iron production, beginning with the year 1810 and continuing through 1933, in the

Bottom left: Puddling process, 18th century.

Bottom right: Early 20th century puddling process.

United States according to the fuel used (charcoal, anthracite, raw coal, coke) was published in *The Iron Age* of Nov. 29, 1934 (page 20 et seq.). In comparing statistics of pig iron production, care must be taken as to the number of pounds in a "ton," whether 2,240 or 2,000 pounds.

The American Iron and Steel Institute, New York, has been the authority on pig iron tonnage or production since the days of the American Iron and Steel Association.

The total capacity of the 225 active iron blast furnaces of the United States reached the peak of 66,256,810 net tons in 1945.

5. WROUGHT IRON.—In 1934, the Committee A-2 on Wrought Iron of the American Society for Testing Materials defined wrought iron as follows: "A ferrous material aggregated from a solidifying mass of pasty particles of highly refined metallic iron with which, without subsequent fusion, is incorporated a minutely and uniformly distributed quantity of slag."

This definition is based upon metallurgical characteristics and is an amplification of the significance of the title, namely, a malleable ferrous material which may be shaped by a forging or related plastic deformation method. Prior to the development of modern steel-making processes—the Bessemer in 1855 and the open hearth or Siemens-Martin between 1862 and 1868—close metallurgical distinctions were not necessary, since wrought iron was virtually the sole ferrous metal adaptable to a forging operation.

Consideration of wrought iron as an entity involves first, the historical aspect, and second, its place in the more recent and contemporary industrial picture.

History and Development.—The origin of wrought iron may be taken as coincident with the earliest record of ferrous products. The limitations of primitive methods of manufacture undoubtedly resulted in a material conforming to the general characteristics of what we now classify as wrought iron.

Iron has been known from prehistoric times. It is frequently mentioned in Egyptian literature, and some samples in the British Museum are believed to date from 3733 B.C. Iron instruments, tools, and weapons were used in Greece in 1400 B.C. and in Assyria and Italy in 1100 B.C. History records their use in central and western Europe in 1000 B.C., and in Styria and Carinthia before the Christian era. The noted Pillar of Delhi is usually assumed to date from 400 A.D. The use of iron was general in Europe in the Roman Empire, and the heat treatment of weapons and tools was practiced at that time.

The Catalan forge, originated about 1293 A.D. by the iron workers of Catalonia in Spain, represented a major advance in the manufacture of wrought iron direct from the ore. This was a hearth type of furnace consisting of a crucible in which the mixture of ore and fuel was placed. The air blast, produced by means of a trompe or water blower, entered the furnace through tuyeres (nozzles) near the bottom. The efficiency of the Catalan forge, which is said to have produced about 140 pounds of wrought iron in five hours, was considerably higher than that of earlier furnaces. It was in use in the American colonies.

The American bloomery, an offspring of the Catalan forge, represented the highest development of the hearth type of furnace. The hearth was rectangular in shape, with water-cooled metal sides, and was surmounted by a chimney for carrying off the waste gases. A forced hot blast was used, the bellows being driven by a water wheel or steam engine. As in all other direct processes, charcoal was used as a fuel. The bloomery was used in the United States as late as 1901.

Although direct processes for wrought iron production have been abandoned almost completely by the most advanced nations, they are still used by primitive peoples in some parts of the world. In all of these methods through the ages, the reduction of the ore produced an iron with a relatively low metalloidal content, a pasty mass at the temperatures attainable. At the same time the gangue of the ore—silica, and other earthy oxides—formed a fluid slag in combination with some of the iron oxide. The product was a weldable sponge or ball intermingled with some of the slag. This was wrought or forged to a bloom for subsequent fabrication. Aside from the relative primitiveness of method in apparatus, manpower and efficiency, it was necessary to use high purity ore and fuel. There was no control of product through secondary reactions which are characteristic of more modern methods of making iron and steel with quantity output of specification grades from large-scale sources of ore and fuel. In the contemporary era, sporadic attempts along the line of direct reduction are faced with the same limitations of control and flexibility, plus economic and engineering factors in competition with today's two-step practice in the manufacture of iron and steel.

About 1350 in central Europe, a revolutionary transition in the iron industry was instituted. The apparatus developed was known as a *stuck-ofen* and was the progenitor of the modern blast furnace. The development was the result of efforts to reduce the fuel consumption and cost of manufacture by increasing the size and height of the furnace with a shaft type of furnace. There was no thought of a changed product, but the alterations of customary conditions, the somewhat higher temperatures, and the longer and more intimate contact of the charcoal fuel and reducing gases with the metallic iron resulted in a fluid product akin to today's cast or pig iron. Compared with wrought iron, it had a lower melting point, higher fluidity, and was relatively hard and brittle with a granular structure, unlike the fibrous wrought iron. It was of little direct use until the art of casting was developed, but the furnace in the succeeding centuries came into its major role for the production of the pig

iron so important in our modern iron and steel processes.

Throughout the ages, man's greatest need has been for a ferrous product of a malleable, ductile type, which could be formed by plastic deformation, hot or cold, and having a relatively high degree of ductility. With limited use for the cast or pig iron of the *stuckofen* and its offspring, inventive effort was concentrated upon refining the product to the condition of the wrought iron in general demand. An attempt was made to reduce the metalloid content of cast iron (carbon 2.4 per cent, silicon 1.2 per cent) together with manganese and phosphorus, to the characteristics of the forgeable product with metalloid content of the base metal a few hundredths of 1 per cent in each case—notably, in the light of modern metallurgical knowledge, by the virtual elimination of the alloyed carbon.

Charcoal hearths, of which the Walloon, Lancashire, and South Wales are characteristic names, are modifications of the direct reduction hearths. In these forges, known as "fineries," the pig iron was melted with charcoal fuel under the oxidizing influence of a blast issuing from a single or double tuyere. The metal, relieved of its oxidizable metalloids, trickled to the bottom of the hearth and solidified to a spongy mass with slag impregnation and was removed as a wrought iron bloom. These furnaces have been used to produce a so-called charcoal or knobbed iron from iron or steel scrap as a starting metal.

General inefficiency of prevailing equipment and methods and, more particularly, the heavy drain upon timber reserves because of the necessity of charcoal for fuel were a serious handicap to the development of the iron industry. Some relief came in 1730–1735 with Darby's use of coke made from England's abundant coal.

The divorcement from charcoal became complete with the invention, by Henry Cort in England in 1784, of a method which has continued to the present era and is known as the "puddling process." This marked an important epoch in the metallurgy of iron. To make the use of more impure but cheaper fuel possible, Cort proposed to conduct the refining of the pig iron in the hearth of a reverberatory furnace, out of contact with the fuel itself and its contaminating influences. The fuel was burned in a separate firebox, the substance to be treated coming in contact only with the flame and gases resulting from the combustion of the fuel. Cort's hearth was sand-lined, and the process came under the name of "dry puddling." The siliceous hearth caused a heavy waste of iron. Marked improvement came with the introduction of an iron oxide bottom by Joseph Hall in England in 1830. This was the inception of the "wet puddling" or "pig boiling" process. It has remained as the puddling process substantially without change to the present and, prior to the entry of the Bessemer and open hearth processes, it was the bulwark upon which war, industry, and the needs of construction rested.

Puddling.—The puddling furnace is a simple, reverberatory, coal-fired furnace, sometimes with a waste heat boiler in the stack. In the Pittsburgh district, the single furnace was used with a charge of about 600 pounds. It was manned by two puddlers. In the eastern United States, double furnaces were the rule. These were really two single furnaces, back to back, with the walls

removed to make a single hearth with one stack. The charge of 1,200 to 1,300 pounds was worked by four men, two on each side. The furnaces had a cinder (iron oxide) bottom, and were lined with plastic iron ore. The charge was cold pig iron and required about one and three-quarter hours for completion of the heat. Five heats constituted a turn with a man-turn output of about 1,400 to 1,500 pounds. The fuel requirement with a long flame, bituminous coal was 2,600 to 2,800 pounds per gross ton of product. The furnace temperature was about 2600° F. After the pig iron had become molten, some iron oxide in the form of mill scale was added to the bath. This caused progressive elimination of the undesired metalloids—silicon, carbon, manganese (almost completely), and phosphorus and sulphur to some degree—depending upon operating conditions. The oxides of silicon, manganese, and phosphorus combined with iron oxide from the scale and from the "fettle" (lining) to form a fluid slag of highly basic nature, essentially about 80 to 85 per cent iron oxide and 10 to 15 per cent silica, with small amounts of the oxides of manganese, phosphorus, and aluminum. The carbon, last to be removed, came off as a gas, bubbling through the liquid bath as the so-called "boil." In the final stages of lessened intensity of the boil, the iron "came to mature" and "grained." This was the completion of refining to virtually pure iron, with a melting point considerably above the operating temperature of the furnace and the progressive solidification of the refined metal. Throughout the reaction period and particularly during the boil, the heat was rabbled with long bars through the side door of the furnace, to aid in disintegration of the mass and permit thorough exposure to the refining influences.

The final spongy metallic mass in the liquid slag was compacted into two or three "puddle balls" which were removed from the furnace with tongs, squeezed to a cylindrical bloom, then rolled on the initial heat to rough, rectangular muck bars. In these operations, surplus slag was ejected, and the characteristic fiber of wrought iron was produced by a threadlike elongation of the slag filaments in the metal matrix. For most commodities, the muck bar was sheared to appropriate short lengths, piled, heated to welding, and rolled to desired "single refined" sections. For some commodities, piling and rolling were repeated to obtain greater reductions, finer slag distribution and higher resultant ductility in the product thence classed as "double refined" iron.

Mechanical Puddling.—Prior to the advent of the age of steel, marked by the introduction of the Bessemer and open hearth processes, some attempts were made to attach mechanically operated rables to the puddling furnace to reduce the arduous labor. Also much effort was expended on mechanical puddling, with machines to carry out the entire operation. A conspicuous example in America was the Danks furnace of 1870. Steelmaking was expected to put puddling and wrought iron into oblivion, and efforts for improvement in manufacture waned. Persistent recognition of the merit of wrought iron in certain services, notably against corrosion and fatigue stresses, furthered it despite limitations in manufacture and caused a revival of interest in mechanical puddling.

Mechanical methods have usually employed furnaces of a rotary or oscillatory type, with atten-

tion focused upon obtaining agitation of the charge in simulation of the manual effort of the puddler. Failures have been caused by inconsistencies in quality of material produced, difficulties of maintenance of equipment, and comparative manufacturing costs unattractive for capital investment. The names of James P. Roe, W. C. Ely, Ford and Henry D. Hibbard have been associated with these methods, some of which reached commercial scales of production.

The revolving furnaces have had their most successful application in "bushelling," that is, heating iron or steel scrap to form a ball which is squeezed and rolled into muck bar for so-called "common iron," a product somewhat below quality grade.

Modern Practice.—An outstanding operation for the production of wrought iron is that of the A. M. Byers Company in the Pittsburgh district. It was the result of a careful study of the metallurgical features of wrought iron, followed by long experimental effort to reproduce the quality characteristics in a controlled and economical manner. The integral steps involved: (1) refining a pig metal charge to a low metalloid content—Bessemer, open hearth or electric steel processes; (2) production of and melting the desired slag, done without difficulty in modified standard furnaces from iron oxide and silica ingredients; (3) disintegration and solidification of the metal and incorporation therein of the desired slag: the crux of the process; (4) compacting the composite mass and squeezing out surplus slag. The result is a product conforming in all respects to characteristics of quality wrought iron. The existing plant began operations in 1930. With the present lack of a blast furnace for supplying direct metal, pig iron of standard Bessemer grade is melted in cupolas. Desulphurization is effectively accomplished with soda ash or caustic soda in the cupola transfer ladle, so that a sulphur content of 0.03 per cent, or lower if desirable, is regularly obtained. This molten pig metal is full blown in 10-ton acid Bessemer vessels to a carbon content of about 0.06 per cent, with silicon and manganese virtually nil.

Shooting.—The required slag conforms to quality wrought iron standards and is melted in a battery of powdered, coal-fired, rotary furnaces. These have replaced the former tilting, open hearth type furnaces. The slag ingredients are roll scale, iron ore, and sand. The molten slag is teemed in the batches required from time to time for the make-up needs of the operation. "Shooting" is the key operation. The blown metal is poured in a steady stream at a rate of one ton per minute into a deep bath of molten slag in large, unlined ladles carried by cars on a circular transfer track. With ample volume of slag at a temperature maintained well below the freezing point of the refined metal, continuous solidification of the metal takes place. Accompanying this is the liberation of all of its dissolved gases with sufficient force to disintegrate the metal and produce a spongy ball of iron, impregnated with the liquid slag. In modern practice the general size of bloom is three to four tons, produced on an approximate 15-minute heat cycle. At appropriate stations the large surplus of slag is decanted into another ladle, and the sponge ball is dumped into a squeezing press. There it is compacted, at welding heat, into a rectangular bloom which, after reheating,

is rolled on a standard blooming mill to billets or slabs. The heat exchange in the shooting operation permits immediate re-use of the decanted slag, with melting only for make-up requirements. The output of modern plant is from 800 to 1,000 tons per day. Most of the product, such as skelp, plate, etc., is rolled from solid sections, in marked contrast to the older wrought iron practice of building muck bar piles. Stay bolts, engine bolts, and locomotive forgings of double refined quality are still rolled from heavy slab piles. The process is under complete control in each of the integral steps and in the chemical and metallurgical characteristics of the materials and product. The wrought iron produced meets all specification requirements and finds outlets as welded pipe, sheets, plates, bars, and forging stock.

Wrought iron finds product applications because of inherent properties of ductility, ease of working and welding, and superior resistance to customary services involving corrosion, shock or fatigue conditions. Mechanized production broadens its horizon if quality standards are maintained.

6. MALLEABLE IRON.—Malleable iron (malleable cast iron or American malleable cast iron) is a ductile cast metal produced by the heat treatment of a graphite-free cast iron.

History.—Cast iron is easy to produce in any required form by pouring liquid metal into a suitable mold and letting it freeze, but it is without ductility. Wrought iron and steel possess ductility but originally had to be forged to shape. Malleable iron was invented to combine the two properties at a time when steel castings were unknown.

The absence of ductility in cast iron is due to the presence of a relatively large amount of carbon, from 2 per cent to 4 per cent of the metal. This may be present in either or both of two forms: graphite and cementite. The former is the element carbon and in the gray cast irons is present in flakes, resembling crumpled pieces of paper or tin foil. Once present, nothing short of melting can be done to overcome its em-

brittling effect on the metal.

Being in flakes, the graphite interrupts the continuity of the metal much more than does an equal amount of graphite in the nodular form found in malleable.

Cementite is an iron carbon compound having three atoms of the former to one of the latter and represented by the symbol of Fe_3C . Its extreme hardness and brittleness account for these properties in white cast iron. This effect can be overcome by heat-treatment.

Two processes have been invented to convert white cast iron, not containing any graphite which would permanently impair ductility, into malleable iron which is reasonably ductile.

The process first discovered in Europe removes the carbon from the metal, reasonably completely. This is accomplished by holding the castings a sufficient time, dependent on their thickness, at temperatures in the neighborhood of 1800°F ., while packed in iron ore. The ore furnishes oxygen which combines with the carbon to form carbon monoxide which escapes as a gas. The reaction:

represents its principle and not its complete sequence of steps. The inventor of the process is no longer known, but it was described by the French physicist René Antoine Ferchault de Réaumur in 1722 without pretense of originality. Such malleable iron is called "white-heart" from the color of its fracture and is still an important article of manufacture in Europe.

On July 4, 1826, Seth Boyden of Newark, N. J. found that he could make a metal which he described in his diary as "dark in color and tougher than any I have yet seen." Since he worked before the days of metallography, he did not know that he was working on a new metallurgical principle, namely, the spontaneous dissociation of iron carbide at temperatures well below the freezing point.

The flaky graphite of gray iron attains its form while crystallizing at a temperature near the freezing point of the alloy where the soft and plastic metallic matrix exercises little or no restraint on its growth into thin platelike forms. In Boyden's process the temperature is low

enough to make the graphite grow in more compact and nearly equiaxed masses called "temper carbon." The product is called "black-heart" malleable and is invariably used in the United States.

Some antiquarian evidence has been offered that black-heart malleable was made in Scandinavia in the 14th century, but the proof is not convincing enough to overcome all doubt.

In modern practice the two processes are not completely separable. The decarburization of the white-heart process is usually accompanied by some graphitization, and the graphitizing reaction in the black-heart process involves some incidental decarburization.

Uses.—In the United States malleable castings are used preponderantly in automotive parts because of their great ease of machining along with strength and ductility. For similar reasons, they are also used very extensively as pipe fittings. Other important uses are in agricultural implements, railway track and trolley parts, certain types of chain belts, and a great multitude of minor applications. The maximum production at the peak of each of the two world wars was approximately at the rate of 1,000,000 tons per year, exclusive of pipe fittings.

Methods of Manufacture.—In its early experimental stages the white cast iron for malleablizing was produced by melting in crucibles. Rather soon the reverberatory furnace came into use in America for melting the white cast iron. These furnaces grew in size from capacities of 500 or 1,000 pounds to capacities of about 40 tons. Reverberatory furnaces were originally hand fired with coal, but now the use of either pulverized coal or oil mixed with air in suitable burners is practically universal.

To the makers of white-heart malleable, high carbon and sulphur content is not particularly objectionable since the former is to be burned out anyway and the latter retards graphitization, and they have adopted the cupola as a measure of economy. The cupola has also commended itself to the makers of pipe fittings as an economical way to produce sound and leakproof castings.

For automotive, railway, and other uses, lower carbons are desired than the cupola can produce, because the more temper carbon nodules that exist in an object, the weaker it will be. To combine the economy of cupola melting with the convenience it offers of producing a continuous supply of metal, the practice of feeding a reverberatory furnace not with solid iron but with liquid cupola iron and of taking off a steady stream of liquid metal has been adopted.

An alternative is to reduce the carbon and otherwise to adjust the composition of cupola metal in electric furnaces. To these two "duplexing" processes may be added a technique, now discontinued, of mixing cupola metal and liquid Bessemer steel in an electric furnace in a "triplexing" operation.

The white iron castings are then heat-treated. For the white heart process this is almost invariably done by packing them in a mixture of hematite ore, which has been previously used, and some new ore to make up for the oxygen expended during these previous uses. The containers are white cast iron pots or boxes. These are heated to approximately 1800°F . and maintained at this temperature for the requisite time which, for example, may be from 6 to 10 days.

Showing malleability of malleable iron automobile parts.

The time to decarbonize a casting completely is approximately proportional to the square of its thickness. This introduces difficulties when castings of various thicknesses are annealed together, for after the carbon is completely gone, oxidation of the iron must be feared. The matter becomes still worse when a single casting varies greatly in cross section. Attempts were made in 1945 to decarburize in a muffle through which a gas of suitable composition is caused to flow. It is possible to select compositions which will oxidize carbon but not iron, and to produce them by the incomplete burning of coal gas.

The black-heart process requires no chemically active packing since the reaction does not involve any outside agency. Graphitization goes on simultaneously at all points in a casting. Its rate is determined primarily by the rate of diffusion of carbon in iron, which varies with the temperature, and by the number of nodules which can be formed, being a function of grain structure. Both may depend on chemical compositions. Heat treatments represent a holding at 1700° to 1800° F., followed by slow cooling to below the critical point (usually about 1300° F.) and sometimes a subsequent holding of that temperature.

According to the composition, the quality requirements, the size of the annealing furnace charge, and the type of furnace, heat treatments vary widely in time. An overall time of about 24 hours is claimed, although it is unusual; 32 to 44 hours may be encountered; 65 hours is quite common, but muffle furnaces of large capacity may require 6 to 8 days. Since to anneal rapidly, small charges and highly mechanized furnaces are required, there is some incompatibility of low cost and fast times.

The simplest furnaces are similar to those used in the white-heart process: the large brick chambers into which stacks of pots containing castings are set, and into which flame passes from pulverized coal, oil or gas burners. For rapid handling, the bottom of the furnace may be a flat-topped car on which the pots stand. Cars can be pulled out and pushed into a cooler furnace without losing much of the heat contained in the furnace structure.

In continuous kilns, cars loaded with pots pass down a long tunnel, fired at intervals, so that as the charge passes through, it remains at each temperature the desired time. Large castings are often not packed in pots but placed in muffles of firebrick or silicon carbide to protect them from the flame. The muffle is then heated from the outside. In view of the long heat treatments, some means of protecting the castings from too oxidizing gases is necessary.

Chemical Composition.—The composition of the hard iron for conversion into black-heart malleable depends upon many factors. Carbon is adjusted from considerations of strength and may be from 2 per cent to 3 per cent. Silicon is desirable as it accelerates graphitization in annealing, but if too high, will cause "primary" or flaky graphite to form during freezing, and thus ruin the product. Small castings may have more silicon than large ones, since primary graphitization is greater with slow freezing. Silicon may be as high as 1.65 per cent under very favorable circumstances, and as low as 0.90 per cent for many large castings. Manganese is usually adjusted to three times the sulphur and the latter accepted as produced according to the melt-

ing process.

Phosphorus is found in amounts ranging from 0.08 per cent to 0.20 per cent. It strengthens the metal, but a combination of high phosphorus and silicon predisposes the metal to intergranular brittleness under impact. This can be overcome by quenching from 1250° F., but brittleness at sub-zero temperatures will remain.

High carbon and phosphorus make it easier to cast small sections, but the former reduces strength and elongation. Silicon, up to that amount which causes graphitization during freezing, is advantageous because it makes for faster annealing.

The only alloys useful in improving the properties of malleable iron are copper and molybdenum. Small amounts of copper increase the resistance to acid corrosion. Larger amounts, up to 1.50 per cent, increase the strength, especially of high-carbon iron. Copper slightly accelerates the graphitizing rate and is therefore often used in connection with molybdenum, a slight retarder, since both increase the strength of malleable iron.

In white-heart malleable, carbon and silicon control are not so important, provided only that primary graphitization is avoided. Either manganese is kept much lower or sulphur is kept higher than in black-heart. Manganese usually does not exceed the sulphur. Phosphorus is generally kept lower in white-heart than in black-heart, usually below 0.10 per cent.

Mechanical Properties.—Specifications adopted in 1939 by the American Society for Testing Materials for black-heart cupola malleable iron require a tensile strength of 40,000 pounds per square inch, a yield point of 30,000 pounds per square inch, and an elongation of 5 per cent. The same society's specifications, adopted in 1933, and reaffirmed in 1944, provide for two grades. One has a required tensile strength of 50,000 pounds per square inch, a yield point of 32,500 pounds per square inch, and an elongation of 10 per cent; the other, a tensile strength of 53,000 pounds per square inch, a yield strength of 35,000 pounds per square inch, and an elongation of 18 per cent. These properties are inseparably related to a particular form and size of test specimen prescribed and identical for all three specifications.

The grade of lower strength and elongation is the more machinable, and the impact resistance of the two last-named grades is about equal. Malleable iron has very high magnetic permeability and is well suited to magnetic circuits using direct current. Like all unlaminated cores, its eddy current loss is relatively high. Alone among the commercial forms of iron, black-heart malleable's elongation changes directly and not inversely with tensile strength. Its machinability is better than that of any ferrous material of similar ductility.

The mechanical properties of white-heart malleable are described by British specifications adopted in 1927. Round specimens 0.564 inch in diameter are required to have a tensile strength 44,800 pounds per square inch and an elongation of 5 per cent in 2 inches. A bar 1 inch by 3/8 inch in cross section is required to bend 45° around a mandrel of 1-inch radius.

Pearlitic Malleable.—This is a term chosen with insufficient respect for the exact meaning of terms. It is used to designate malleable iron purposely containing combined carbon, whether

this is present as pearlite or in some other metallographic form. These materials are produced by one of three types of processes. Starting with white cast iron identical with that used for black-heart malleable, the annealing cycle may be shortened, particularly near the critical points, in order to leave the desired amount and form of combined carbon. Alternatively, chemical elements retarding the graphitizing process, such as manganese, molybdenum or chromium, may be added to the white molten cast iron as required, in order to produce the desired result, after a normal annealing cycle or a modified one. Lastly, malleable iron may be heated above the critical point, to 1480° F., for example, where graphite will redissolve very quickly in an amount determined by the temperature. The material is then cooled in such a manner as to produce the desired structure.

Since innumerable combinations of techniques are available, it is not unnatural that the properties of these so-called pearlitic malleables will vary widely. All are stronger, less ductile, less machinable, and harder than malleable. All of them are also of higher electrical resistivity and lower magnetic permeability. The ductility which can be had for a given strength depends very largely on the properties of the original, completely annealed malleable in those pearlitic malleables which are produced by reheat-treating that product.

Three quite important types of microstructure are found in the matrix of pearlitic malleable. This matrix, in which the temper carbon is imbedded, consists of two metallic constituents: carbon-free iron or ferrite, and iron car-

bide or cementite. The form of the latter is greatly variable. In some pearlitic malleable the carbide is somewhat uniformly dispersed through the ferrite. In another type the graphite nodules are surrounded by "bull's eyes" of carbide-free ferrite, the remainder of the structure consisting of a somewhat uniform dispersion of carbide in ferrite. In the third type, the matrix consists of ferrite grains, separated by a network of carbide dispersed in ferrite.

As these patterns change, the resulting properties also change greatly. Pearlitic malleables may have ultimate strengths of over 100,000 pounds per square inch with very low elongation, 1 per cent or 2 per cent, for instance. At the other extreme is the correlation of strength and elongation found in ordinary black-heart malleable.

There are no analogues to these pearlitic malleables among the white-heart malleables. If decarburization is there incomplete, the centers of heavy sections are pearlite, in extreme cases interspersed with massive carbides. This condition, however, is not desired and is not tolerated in sections which are to be subject to severe usage.

Welding Malleable.—Since black-heart malleable reverts to pearlitic malleable on heating above the critical point, welding processes are limited to procedures involving either the use of very low melting electrodes, which frequently lack strength, or to the use of subsequent, accurately controlled, heat-treatments to undo the effects of reheating in welding. Completely decarbonized, white-heart malleable can be welded in the forge fire or by any of the methods applicable to low-carbon steels.

Graphitizable Steel.—Since about 1937, alloys which are sufficiently low in carbon as to be properly classified as steel and high enough in silicon to graphitize readily have come into use. Their composition may be about 1 per cent carbon and 1.25 per cent silicon. They are most frequently used in modifications analogous to the pearlitic malleables and find their principal application in automotive construction.

7. ORIGIN OF IRON ORES.—Iron ores are those parts of the earth's crust from which iron can be extracted at a profit. Whether or not an iron-bearing rock is ore depends upon many factors, chief among which is the demand as reflected by the price of ore. As the price goes up, materials that were formerly not ore, either

Magnified structure of pearlitic malleable iron.

because of their low quality, undesirable impurities, unfavorable geographic situation, or for other reasons, become valuable. New methods and techniques for cheaper mining and better recovery also result in lower per-unit costs. Thus the rock of today is the ore of tomorrow. Iron ore is a cheap commodity that is handled in bulk. Because of this fact the size of the ore bodies is of prime importance, as the unit cost of handling large tonnages is considerably less than it is for small amounts. The presence of impurities such as silica, nickel, chromium, and copper, even in small amounts, frequently determines whether or not a material is ore.

Iron Formation.—The term "iron formation" is used in reference to a banded or layered iron-rich rock of sedimentary origin. In the Lake Superior region this formation is called taconite, and in Brazil it goes by the name of itabirite. The individual beds or layers are generally less than one inch thick and consist of chert (silica) and an iron-rich mineral—oxide, carbonate, sulphide, or silicate. In places the individual layers gradually disappear. The rock grades into ferruginous shale or slate, or into quartzitic beds, and locally into massive hematite.

Iron formation is widely distributed throughout the world. Some of the better known districts include the Lake Superior region in the United States and Canada, the Ungava Bay region in Labrador and Quebec, El Pao and Cerro Bolívar in Venezuela, the Brazilian deposits near Belo Horizonte in the State of Minas Gerais and near Corumbá in the State of Mato Grosso, the Bomi Hills in Liberia and elsewhere in Africa, in India, the Yampi Sound in Western Australia, in Manchuria, and at Krivoi Rog in the Soviet Union.

Most geologists agree that the layered character and other features of the iron formation indicate a sedimentary origin. Four principal theories have been advanced to explain the accumulation of the iron-rich sediments: (1) The silica and iron accompanied volcanism and probably came from magmatic springs that were poured out on the sea floor. (2) Iron and silica were brought in solution from a nearby land mass and were rhythmically deposited as sediments in water, probably as a consequence of seasonal variations in the composition of the water. Deposition resulted either by direct chemical precipitation of silica and iron or by organic agencies. (3) The beds were originally deposited as fine-grained ferruginous tuffs and other normal sediments. The beds were silicified, more or less contemporaneously with their deposition, and gave rise to banded cherts and jaspers. The cherty nature of the silica was determined by the low-temperature conditions of deposition. (4) The iron formation represents accumulations in a partly enclosed basin, and precipitation and character of the sediment were controlled by oxidation-reduction conditions.

The ultimate source of the millions of tons of iron included in these rocks may have been the interior of the earth, from which iron-bearing waters were ejected during volcanic activities, or the iron may have been contributed to the sea by streams which received their iron from deeply weathered land masses. Iron formation is ordinarily not ore because the silica content is too high and the iron content, which ordinarily ranges between 15 and 35 per cent, is too low for profitable mining.

In nature, iron formation is converted to iron ore in any of several ways. Under conditions of tropical weathering, silica, being more soluble than iron, is slowly removed and leaves behind a deposit of high-grade iron ore. Leaching of silica is also accomplished by warm water that accompanies volcanic and similar igneous activities in the earth. Where iron formation has been deeply buried and subjected to mountain-making forces, the iron and silica locally separate, and the iron may be concentrated in masses of hard, compact ore. Where iron formation is partly weathered and is softened, the silica particles are easily separated by screening or by jigging, and a useful concentrate is recovered.

Taconite.—The iron formation or taconite of the Lake Superior region, and especially the hard siliceous and partly magnetic taconite of the eastern Mesabi Range in Minnesota, has long presented a challenge to the iron and steel industry. Here is a tremendous supply of at least five billion tons of low-grade iron-bearing rock readily available to existing transportation and smelting facilities. This hard tough taconite cannot be drilled effectively by ordinary methods, and only within recent years has a new method of drilling, called jet piercing, been developed. In this method, jets of flame, produced by a mixture of oxygen and petroleum base fuel, spurt from a rocket-type burner and cause the rock to chip. Steam from cooling water flowing to the burner flushes away the flakes as the drilling progresses. On the average, jet piercing drills a 6½-inch hole about 15 feet an hour in the hard taconite.

After blasting, the taconite is finely ground and is concentrated magnetically to a powder that contains 60-65 per cent of iron. The fine powder, dampened, is put into a rotating drum, from which emerges a stream of mud balls or pellets, each about one inch in diameter. After burning at a high temperature to assure that they will not dry out and crumble, the pellets are ready for the blast furnaces. They form an ideal furnace feed and are much sought after. The recovery of the iron in magnetic taconites assures the Lake Superior region of a long period of mining activity after the rich soft ores are exhausted.

The principal difficulties in the way of development of the taconite industry are the many millions of dollars and the length of time required to construct large recovery plants. Another factor in the taconite industry is that production of pellets cannot be rapidly expanded during times of pressing economic need. While the recovery of magnetic taconite will continue to expand the process of treatment will be improved, the demands for iron and steel are so tremendous that ore necessarily will be obtained from all available sources. Magnetic taconite will furnish a steadily growing supply of high-grade material to the blast furnaces, but alone will not be an adequate substitute for the larger and more easily handled soft-ore bodies.

At the Republic and Humboldt mines in the Marquette Range, hard siliceous hematite-bearing taconites known as jasper ore are being mined. After grinding, the hematite is concentrated by a froth-flotation process. The concentrates are then pelletized in much the same manner as the magnetic taconite. The wash ore that was formerly produced in considerable amounts from the western Mesabi Range is another form of partly weathered taconite. Wash ore is super-

ficial material, softened and partly decomposed by weathering processes. It is cheaply mined, then flushed through a screen where coarse silica and the very fine particles are removed. The resulting washed product is a good grade of ore. Other types of taconite, including those in which the iron is in the form of sulphide, silicate, and most of the nonmagnetic oxides, are not at present commercial. The Lake Superior region is the only place in the world where mining and pelletizing of taconites is being done on an appreciable scale.

Oölitic Iron Ores.—Oölitic ores are so called from their resemblance to fish roe. They vary in size up to a diameter of about $\frac{1}{8}$ inch, and commonly show concentric layers around cores of sand or shell fragments. A radial fibrous crystal structure, is exhibited by many oölitic. The oölitic iron ores were deposited in shallow lagoons where sand and shell fragments were plentiful. The water, discharged from the weathering land masses, contained iron bicarbonate and possibly colloidal iron, which were rapidly precipitated in the sea. Hematite, chamosite, and siderite replaced limy oölitic and shell fragments, coating grains of sand and other materials. Among the larger oölitic iron ore deposits are the minette ores of Lorraine and Luxembourg, the Clinton ores of the eastern United States, the Cleveland Hills deposits (Yorkshire, England), and those of the Wabana district in Newfoundland.

The minette ores are brown, yellow, or gray, and are soft and earthy. They form several beds interlayered with shales, sands, and marls. Many of the oölitic consist of limonite and hematite, but others are siderite and chlorite, cemented by a fine-grained matrix of the same minerals. The iron is derived from adjacent land masses and carried to the sea; according to one group of geologists, the iron has replaced the calcium in limy oölitic. Other geologists believe that the oölitic were originally iron carbonate (the mineral siderite) and later were changed to the oxides.

The Clinton ores are best developed in Alabama, but they extend northward irregularly through New York State. They are bright red and, as with the minettes, contain considerable lime. The Clinton oölitic ore consists of small grains of hematite in a lime matrix. Many individual oölitic have cores of sand. Other types of ore associated with the oölitic in the Clinton beds include flaxseed ore, fossil ore, and sandstone ore. The flaxseed ore contains small flat hematite grains about the size and shape of flax seeds. The fossil ore consists largely of fossil fragments coated by, or replaced by, hematite. In the sandstone ore each sand grain is coated with hematite and the grains are cemented by hematite and calcite. The ore was formed by direct precipitation from sea waters. Iron was carried by streams into shallow marine basins and there was slowly precipitated around shells and sand grains. Near the surface, where weathering processes are active, the ores are soft and are easily mined. In depth they are somewhat more siliceous and are harder.

The ores of the Cleveland Hills district in England are shallow marine deposits composed of oölitic of chamosite and grains of siderite in fine-grained chamosite. Originally the ores formed a muddy shoreline in the sea. The Wabana ores are oölitic of hematite and chamosite in a matrix of siderite and other

minerals. Borings of algae penetrate both the oölitic and the matrix. The ore is a shallow marine deposit that was in its present condition before being buried under other sediments.

Other Sedimentary Ores.—Ores such as those of the Watenstedt-Salzgitter area in Germany are believed to be of shallow marine origin, though they do not show oölitic structures. Other marine deposits include the low-grade iron carbonate beds or black band ores of England and the eastern United States.

Magmatic Segregation Deposits.—As molten rocks (magmas) within the earth cool, crystals are formed and settle in the chamber occupied by the molten materials. These crystals in places are iron-rich minerals, and after the magma has cooled and the rock is elevated to the surface of the earth, they accumulate locally in layers rich enough to mine. Such layers, formed by crystal settling, by convection currents, or by other processes of concentration within the magma, are called magmatic segregation deposits. The titanium-rich iron ores of the Allard Lake district, Canada, are of this type.

Other iron ores are closely related to magmatic segregation deposits. After crystallization in a magma has proceeded nearly to completion, it is possible that considerable iron is left in the residual fluid, which rises to the top of the magma chamber. As cooling continues, the fluid fills the interstices among the crystals near the top of the cooling mass. After solidification, the interstitial material may contain sufficient iron to be ore. Such is possibly the origin of part of the magnetite ore bodies in the Adirondack region of New York State. Where the final residual liquid, rich in iron, escapes from the solidifying magma and is forced upward by pressure, it is injected into the overlying rocks, and locally forms iron ore. The rich deposits of Kiruna and Gällivare, Sweden, have formed in this manner. They are called magmatic injection deposits.

Black Sands.—Heavy resistant black sands accumulate along many beaches and sand bars. Sands of this type are accumulating today wherever water sorting along streams or beaches takes place. Black sands are known to have formed throughout geologic time, and the old deposits are known as "fossil" beaches and bars. The most prominent constituents of the sands are probably magnetite and hematite, though ilmenite is also common, along with other heavy resistant minerals. Owing to the presence of impurities and to the shallow depths of many deposits in comparison to their surficial extent, the economic value of most sands has been slight. In few places can they be mined economically from iron. Small amounts are recovered from the titaniferous beach sands of northern Honshu and Hokkaido for use in the steel industry of Japan.

Pyrite.—The sulphides of iron, pyrite and pyrrhotite, are widely used in the manufacture of sulphuric acid. The ores are burned, and sulphur is removed as a gas. The residues are fine-grained red powder that ordinarily contain 60 per cent or more of iron. After being sintered to a hard porous clinker, the material is an excellent furnace feed. Sinter of this kind is used in many places. In Japan about one million tons of sinter are used annually in the steel industry, and sinter also forms an important part of the raw material used in European iron and steel mills.

Igneous Metamorphic Deposits.—During cooling of a molten rock or magma, the light

watery constituents escape into the bordering solid rocks. These watery fluids, known as mineralizers, carry iron and other elements with them. Where they encounter favorable chemical and physical conditions in the surrounding rocks, iron is precipitated, principally as the oxides magnetite and hematite, or as the sulphide pyrite. Complex silicate minerals, such as the garnets and hedenbergite, are commonly found with the iron minerals. Deposits formed in this manner are distributed in the country rock around the borders of the crystalline materials. Because of their location they are called igneous metamorphic or contact metamorphic deposits. The iron ores at Cornwall, Pa., are of this type. Here iron ore replaces limestone and limy shale along the line of contact with a dark crystalline intrusive rock called diabase. At Cedar City, Utah, similar conditions are found. The ore is in limestone at the line of contact with a granitoid rock called quartz monzonite. Here iron-rich minerals in parts of the quartz monzonite were altered, and the iron was redissolved in the residual magmatic fluids. These fluids migrated from the intrusive masses outward and upward into the lower energy levels of the surrounding rocks, where they reacted with the limestones and deposited the iron.

Replacement Deposits.—Where iron-bearing fluids migrate through the earth and encounter environments favorable for chemical reaction, the rocks are dissolved and carried away in solution. In their place the iron minerals are deposited. Where deposition follows solution so closely that the original textures and structures are preserved, the deposits are known as replacement deposits. Either hot or cold waters that traverse iron-bearing rocks readily become laden with iron salts. The Steep Rock Lake deposit in Ontario and several of the better ore bodies in the State of Minas Gerais, Brazil, are replacement deposits formed where iron-bearing waters encountered environments favorable for deposition.

Spring Deposits and Bog Ores.—Reddish brown to yellow hydrous iron oxides are deposited at the orifices of many springs and also accumulate slowly in bogs and swampy places. These deposits are generally small and of minor economic value, although a spring deposit at Kuchan, Hokkaido, was of great local value and yielded more than five million tons of ore. Both spring ores and bog ores commonly contain sand grains and other impurities and are high in phosphorus. Limonite is carried in solution with carbon dioxide (CO_2), humic acids, or sulphuric acid derived from the oxidation of sulphide minerals. It is readily precipitated by the loss of CO_2 or by the neutralization of the acid. It forms thin iridescent films on quiet water, which are frequently mistaken for oil.

Weathering Processes.—Any iron-bearing rock exposed at the surface of the earth is subjected to atmospheric attack. The more soluble constituents are removed, and iron in the form of limonite accumulates along the outcrops. In places this limonite has been mined for ore, and exposures of weathered sulphide deposits have been especially worthwhile. A deposit of this type was mined at Ducktown, Tenn. At Cartersville, Ga., the ochre and amber, sought for use in the manufacture of pigments, are fine-grained mixtures of limonite and clay that were left in pockets on the rough surfaces of the rock at the base of the zone of weathering.

Laterite.—Residual mantles of iron-rich soil,

called laterite, are found in many places in the tropics. They have been mined locally, though in general they are of small economic value in the iron-ore industry. Laterites ordinarily consist of iron oxide pellets one inch or less in diameter, scattered through dark red to yellow soil rich in iron. They are residual materials left after the long-continued weathering of iron-rich rocks in warm and humid climates. Laterites are porous bulky ores that contain much water and generally have about 30 to 45 per cent of iron, though exceptional ores contain more. Because of their low grade, and especially because of their water and irregular contents of chromium and nickel, laterites are not now used in blast furnaces. Nickel is recovered from laterites in New Caledonia, at Nicaro in Cuba, and at Riddle, Ore., though the iron is not used. With the depletion of the high-grade ores of the Lake Superior region and with the tremendously increased demands for ore, considerable attention is being given to laterites, and it seems likely that they will become a valuable supply of ore. Many laterites are favorably situated for cheap mining and transportation, and reserve deposits are estimated in many billions of tons. For bibliography, see 9. *World Supplies* (Bibliography).

CHARLES F. PARK, JR.,

Department of Geology, Stanford University.

8. IRON ORE DISTRICTS OF THE UNITED STATES.—The iron ore industry of the United States was established along the Eastern seaboard during early colonial days. It was based primarily upon brown iron ores that extended along the eastern foothills of the Appalachian Mountains, and upon charcoal that was made near the furnaces. The industry furnished adequate iron and steel for the modest demands of the period. The gradual westward migration of population, increased industrialization, and improvements in ironmaking resulted in greatly increased demands for iron and steel. The Eastern seaboard could no longer fulfill the needs of the country, and as a result iron mining gradually shifted to the larger deposits of the Lake Superior region and to Birmingham, Ala. Large integrated steelmaking centers, using these ores, were established near adequate supplies of coking coal. The great industrial expansion in the United States since World War II and the continuous growth of population have resulted in unprecedented demands for iron and steel. This has resulted in increased production in the East and an even greater expansion in the partly developed Western states. Thriving iron and steel smelting industries exist in Colorado, Texas, Utah, and California. The total iron ore mined in the United States has grown from the small tonnage required in colonial times to about 117 million tons in 1953, and needs continue to expand. Domestic mines have been unable to supply demands, and the United States is becoming increasingly dependent upon foreign ore supplies. Scarcely a deposit of iron-bearing rock in the country has not been examined and explored, and many have been developed.

Lake Superior Region.—The Lake Superior region has been by far the most productive iron ore district in the United States. From its first shipment in 1854, through 1953, the region yielded a total of 2,808,514,542 tons of ore, much of it high grade. Production has come principally from six separate areas or ranges—the Vermilion,

Mesabi, and Cuyuna in Minnesota, the Penokee-Gogebic in Wisconsin and Michigan, and the Menominee and Marquette in Michigan. In addition several smaller deposits, such as those at Republic and Amasa, Mich., and Baraboo, Wis., have contributed to the total production. Ranges in adjoining parts of Canada are also generally included in the Lake Superior region. These are the Michipicoten and the Gunflint, the southern part of which crosses the international boundary into Minnesota. The Steep Rock Lake deposit is also in the Lake Superior region.

The Mesabi range has been by far the most productive. One mine that has probably produced more iron ore than any other in the world is the Hull-Rust-Burt-Sellers open pit. In 1942, its year of maximum production, this pit alone produced 21,535,000 tons of direct shipping ore. On the Mesabi range the iron ores are in the Biwabik formation, which crops out in an east-west direction for nearly 100 miles. Most of the mining has been by open-pit methods and at depths of less than a few hundred feet. The deepest ore mined on the Mesabi range came from a depth of about 900 feet, though elsewhere in the Lake Superior region, as on the Gogebic range, depths up to 4,000 feet have been attained. With the approaching depletion of the rich surface ores, underground mining is assuming greater importance. This is especially true in ranges other than the Mesabi. The change to underground mining takes on special significance in the planning of national defense, as production from underground mines is essentially fixed and cannot be expanded rapidly, as can that from open pits.

The iron ores of the Lake Superior region range widely in their physical and chemical characteristics. They are divided into hard ores and soft ores, each of which is further classified into five types: Bessemer, non-Bessemer, high-phosphorus, manganiferous, and siliceous. Bessemer ore contains less than 0.045 per cent of phosphorus when dried. Non-Bessemer ore contains between 0.045 and 0.180 per cent of phosphorus, and high-phosphorus ore contains between 0.180 and 0.250 per cent. Manganiferous and siliceous ores contain abnormally high percentages of manganese and silica. During the early period of mining much of the ore was of Bessemer grade, but within recent years between two thirds and three fourths of the ore has been of low-phosphorus non-Bessemer type. The iron formation or taconite of the eastern Mesabi Range is a dense, hard, tough rock that contains between 25 and 35 per cent of iron. Where the iron is present as magnetite, extensive development of the deposits is under way. Mining is done in open pits, and production is expected to expand rapidly as treatment plants are completed. Siliceous taconites on the Marquette Range are also being developed, and the iron is concentrated by flotation.

Eastern Ore Deposits.—Birmingham District.—The Clinton formation ranges in thickness from 250 to 500 feet and consists of thin beds of ferruginous sandstone, shale, and oölitic hematite. The formation extends from Alabama northward into New York State and locally contains beds of iron ore that average two to three feet thick. The iron ores attain their maximum thickness in the vicinity of Birmingham, Ala., though Clinton ores have been mined to a lesser extent in Tennessee and elsewhere. Near Birmingham two beds are mined. These each

average between 8 and 20 feet thick and are mined for a distance of about 18 miles along their outcrops. The ore contains a small amount of calcium carbonate and is in part self-fluxing. Near the surface is found soft rich material which makes excellent furnace feed. Mining is all underground, and the deepest workings are about 6,000 feet below the surface. At this depth the ores are hard; they are apparently becoming more siliceous, and are expensive to mine. The mines are close to the excellent coking coals of the Warrior basin; and this, combined with the self-fluxing properties, has enabled the ores to compete with the higher-grade materials from Lake Superior and elsewhere. The Birmingham district has been the second largest producer of iron ore in the United States, after the Lake Superior region, producing annually between 6 and 11 million tons of crude ore in the 1950's; but the district has passed its peak of production, and output is expected to decrease gradually.

Brown Iron Ores.—The brown iron ores extend irregularly southward from Vermont along the Appalachian Mountains to Alabama. These ores consist mainly of limonite nodules in beds of shale and sandstone. They have been used extensively since colonial days, and the supply has been essentially exhausted. The ores were used both as direct furnace feed and as special lump ore. They are still so used when available. At Cartersville, Ga., brown iron ore is used as a source of ochre and umber.

Magnetite Deposits.—Beginning in 1937 several magnetite deposits in the Adirondack Mountains of New York State were developed. A few of the deposits, such as the Clifton, mine direct shipping ore. Most ores, however, contain magnetite grains distributed through gabbro or syenite, and they require concentration before they can be used in furnaces. Both open pit and underground mining methods are employed. Most of the ore contains 25 per cent or more of iron. It is crushed, concentrated magnetically or by other methods, and then nodulized in a kiln to form an excellent blast-furnace feed. New York State produces annually about 3 million tons of concentrates and direct shipping ores. The titaniferous magnetites of Lake Sanford, N.Y., are mined primarily for their titanium content. The residual magnetite, left after the titanium is removed, is sold to various steel plants, where small amounts are mixed with titanium-free ores. New Jersey also contributes between 1 and 1½ million tons of iron ore annually. This is obtained from high-grade magnetite deposits, nearly all mined by underground methods. In Pennsylvania the Cornwall magnetite mine has been operated since 1742, though it has passed its peak of production and its known reserves are limited. Pyrite in the ore at Cornwall contains a small percentage of cobalt and copper, which are recovered as by-products. A new iron ore body at the Grace mine, near Morgantown, Pa., was discovered by airborne magnetic methods of prospecting. Many other small magnetite deposits in the Eastern states have been mined, but at present are of little economic importance.

Western Ore Deposits.—Missouri.—Iron ore production in Missouri has come largely from deposits of hematite with minor magnetite in the Iron Mountain and Pilot Knob districts. Andesite porphyry of intrusive origin is associated with the ores at Iron Mountain. At Pilot Knob the ore replaces sedimentary beds and rests di-

rectly upon porphyry-flow rocks. Nearly half a million tons of ore are produced annually from these districts. Between 150,000 and 200,000 tons of limonite are also obtained annually from filled-sink deposits in western and central Missouri and northeast Arkansas.

Texas.—The brown iron ores of east Texas have been extensively developed since World War II, between 2 and 4 million tons being produced annually. The ores, in unwashed condition, probably average 40 to 45 per cent iron. They consist of abundant nodules and layers of limonite in sand and clay layers, and are mined in open pits. The brown iron ores, smelted with coal from the McAlester district in Oklahoma, form the basis of a small iron and steel industry.

Wyoming.—The principal supply of iron ore for the smelter at Pueblo, Colo., comes from the Sunrise deposits at Hartville, Wyo. The ores are of a regionally metamorphosed banded iron formation similar to the taconites of the Lake Superior region. The best ore is hematite, which is concentrated in lenses of schist near the contact with underlying limestone. Both open and underground mines have been operated, and annual production has been about one-half million tons. Other hematite deposits of minor economic value are known near Seminole and Rawlins.

Colorado, New Mexico, and Arizona.—Numerous deposits of magnetite, hematite, and brown iron ores are widely distributed through these three states. The deposits are all small and without exception are of limited value as known. Several deposits, such as that at Fierro, N. Mex., have been productive in the past, but their ore is considered to be exhausted. Other deposits are too low in grade to permit profitable mining. Total production in recent years has been only a few thousand tons annually. Most of the ore mined in the past was shipped to Pueblo, Colo.

Nevada.—Small deposits of magnetite and hematite have been known in Nevada for many years, and some were mined in the past. It is only since the Korean War (1950–1953) that the properties have been extensively explored. The principal deposits are in the Buena Vista Hills, near Lovelock, but several others have been partly developed. The ore is high grade. Nearly the entire annual production of about 500,000 tons is exported to Japan.

Iron Springs District, Utah.—The Iron Springs district in southwestern Utah was first operated in 1874. It has furnished the principal ore supply to the blast furnaces and integrated steel works at Provo and Geneva, Utah. Lesser amounts of ore have been sent to Pueblo, Colo., and to Fontana, Calif., and a few shipments have been made to Japan. The ore is mainly magnetite with some hematite. It replaces limestone and is found in the limestone where it is in contact zones around three separate intrusive masses. The total reserves of the district are estimated to be in the order of one-half billion tons. The grade of the ore in the past is reported to have been between 55 and 60 per cent iron, though large amounts of it require beneficiation to bring it up to this grade. Annual production in the 1950's was between 4 and 5 million tons. With the increased demands for iron and steel in the Western states, the Iron Springs district is emerging as the principal ore supply available to Western industry. Other deposits of iron ore are known in Utah at Bully Hill and elsewhere, but they are of small size.

California.—About 50 deposits of iron ore are known in California. They are widely distributed throughout the state, and most of the deposits have been partly explored. Both magnetite and hematite deposits are common, and a few small deposits of brown iron ore are known. With a few exceptions the deposits are too small or too poor in quality to permit commercial exploitation. During World War II the Vulcan district in San Bernardino County contributed ore to the blast furnace at Fontana. In recent years ore for Fontana has come principally from Eagle Mountain in Riverside County. This deposit annually produces about 1½ million tons or more. Eagle Mountain is estimated to contain a known reserve of about 25 million tons, with a potential reserve of considerably larger amounts. Other localities, such as that of the Shasta deposit, have been worked for ship's ballast or for other special purpose ores. The deposits known are too small to be profitably operated, or they contain prohibitive amounts of deleterious elements, especially sulphur and phosphorus.

Northwestern States.—The iron ore deposits of the Northwestern states are small and annually yield only a few thousand tons of ore.

The Scappoose brown ores near Portland, Ore., have been explored but apparently have not proved to be economic. In northeastern Washington small amounts of brown iron ore are used in the cement industry. Other deposits are known in central and northern Washington but are not extensively mined. The Iron Mountain deposit and several other small bodies of hematite and magnetite in Idaho have been explored but have not been mined. In central Montana the Sheep Creek brown iron ores and the magnetite-hematite deposits of Wolf Creek are operated in a small way for use in the cement industry. Small amounts of iron ore are also mined in South Dakota, principally from the soft iron ores in the Black Hills. For bibliography, see 9. *World Supplies* (Bibliography).

CHARLES F. PARK, JR.

9. WORLD SUPPLIES.—The rapidly increasing demand throughout the world for iron and steel products has given great impetus to the search for and development of new iron ore bodies. Districts remote from smelting centers are being explored and mined; new and costly methods of beneficiating low-grade materials are being developed and installed. The iron ore industry is keeping pace with the increased demand for steel, though the capital expenditures involved are tremendous. Since the amount of iron ore mined near the large steelmaking centers is no longer adequate to meet the increasing demand, despite generally increased production, other sources of supply must be developed. The trend in the United States, and to only a slightly lesser extent in Europe, is toward increasing dependence upon foreign, and in large part remote, supplies. This trend is expected to continue. Among the larger deposits developed since World War II are the Ungava Bay region in Labrador and Quebec, Cerro Bolivar in Venezuela, Romeral in Chile, Marcona in Peru, and the Bomi Hills in Liberia. In addition to iron ores, approximately 6 million tons of highgrade hypocrud iron sinter are used annually to supplement the available ore in the United States alone. Scrap iron constitutes another invaluable source of raw material for the furnaces.

North and Central America.—In North America, outside of the United States, large amounts of ore have been produced from the high-phosphorus oölitic hematite in the Wabana district of Newfoundland. This ore, because of its high phosphorus content (up to 2 per cent phosphorus), is shipped to Europe, where it is reduced by the Thomas process. The deposits contain an estimated reserve of about 3 billion tons with a grade of between 48 and 57 per cent iron. The Michipicoten range, on the Canadian side of Lake Superior, has maintained a small but steady production for years. Since 1944-1945, exploitation of the Steep Rock Lake deposits in the Atikokan range in southern Ontario has expanded continuously after the successful diversion of a river and the draining of Steep Rock Lake. These deposits are thought to contain about 600 million tons of ore. Hematite deposits in the Ungava Bay region of Labrador and Quebec have been developed and have attained an annual production of about 10 million tons. These deposits are estimated to contain a reserve of about 2 billion tons and are expected eventually to produce 25 million tons yearly. A standard-gauge railroad now connects the mines

with new port facilities on the St. Lawrence River, and the ore will be readily available to the Great Lakes steel centers upon completion of the St. Lawrence Seaway. The Marmora and other small properties in Ontario and in nearby Quebec contribute considerable production annually. In western Canada deposits on Vancouver Island, Texada Island, and elsewhere in British Columbia produce small quantities of ore for the export trade to Japan.

Several magnetite-hematite deposits are known in Mexico, but few of them have been developed. Probably the best known are at Cerro de Mercado, north of Durango, which yield sufficient ore to maintain a small smelting industry. Other magnetite-hematite deposits, such as those of El Vulcan, Las Truchas, and Aguililla, are known in the State of Michoacán in western Mexico and elsewhere in Mexico and Central America, especially in Nicaragua and Honduras. The laterite deposits of Cuba, especially those along the northeastern part of the island, constitute a tremendous reserve of potential low-grade ore. Efforts to produce uniform steel products from these laterites have so far been uneconomic, largely because of variable amounts of nickel, chromium, and water in the ore.

South America.—Among the largest and richest iron ore reserves in the Western Hemisphere are the deposits near the city of Belo Horizonte in the State of Minas Gerais, Brazil. These deposits are about 325 miles inland from the ports of Vitória and Aracruz (formerly Santa Cruz), and about the same distance north of Rio de Janeiro. Estimates of available reserves range up to 15 billion tons, containing about 35 per cent iron. Much smaller tonnages are higher in grade. The well-known deposits at Itabira export between 2 and 3 million tons of high-grade lump ore annually to the United States and to Europe. Ore from the deposits at Casa de Pedra is transported by rail southward. It furnishes most of the ore for the Brazilian iron and steel works at Volta Redonda. Many other small properties contribute to the export ores, which average between 55 and 69 per cent of iron and are low in phosphorus and sulphur. Other large deposits are in western Brazil near Corumbá on the Paraná River in the State of Mato Grosso. This ore is remote from any steel-making center, and is undeveloped except for small pits that furnish ore to local charcoal furnaces.

Within recent years Venezuela has become one of the principal exporting countries for iron ore in the Western Hemisphere. The largest deposit is at Cerro Bolivar, about 91 miles south of the Orinoco River on the west bank of the Caroni River. This deposit is estimated to contain at least 400 million tons of ore, and production facilities are designed to handle more than 10 million tons annually. The deposit at El Pao has published reserves of 70 million tons and annually exports between 2 and 3 million tons to the United States. The grade of Venezuelan ore averages about 60 per cent iron, and the total estimated reserves of the country are about 2 billion tons. Venezuela is an important supplier of iron ore to the United States, and it is expected to maintain and to improve its position.

Iron ores are known at many places along the western coast of South America. In Peru the deposits at Marcona contain large tonnages of ore. These deposits, developed in 1953, are expected to assume increasing importance.

In Chile the famous deposit at El Tofo has been exhausted, but new deposits at Romeral near Coquimbo are now in production. The large deposit at Algarrobo in the desert of northern Chile is as yet undeveloped. Chilean deposits supply ore for the steel mills at Huachipato in central Chile and also export a million or more tons annually to the United States. In addition to the high-grade deposits in South America, large tonnages of potentially valuable laterites exist at many places in the tropics.

Europe.—Europe contains several large deposits of excellent iron ore, as well as many smaller deposits and others of marginal grade and character. Because of the wide distribution of iron and steel works and the excellent system of transportation in Europe, ores are mined and treated that would be uneconomic in other parts of the world. Deposits, well known in the past, such as the famous districts of Bilbao in Spain, Eisenerz in Styria (Austria), the Lahn-Dill and Sieg river valleys in Germany, and the Banat district in Rumania, are long since past their peaks of production, though small amounts of ore continue to be mined. Many of the European ores are high in phosphorus and are smelted in the Thomas basic open-hearth furnaces. In this process the phosphorus is recovered from the slag and used in fertilizers.

Probably the largest single source of iron ore in Europe is the minette ore of Luxembourg and Lorraine. These deposits have long been the backbone of the European iron and steel industry. They are estimated to contain a reserve of as much as 15 billion tons, which is low grade, containing an average of between 30 and 35 per cent of iron. The ore is also high in phosphorus, 1.6 to 1.8 per cent. Where iron content decreases, the lime content generally increases. Sufficient lime is present to make much of the ore self-fluxing, and little or no additional limestone must be added during smelting. France also produces small amounts of ore in Brittany and in Normandy.

In Germany the Watenstedt-Salzgitter-Peine deposits are said to contain a reserve estimated at between 1 and 2 billion tons. The ore averages only 29 to 33 per cent iron, and is high in both phosphorus and silica. Several smaller deposits are also exploited in Germany.

The highest-grade ores in Europe are found in northern Sweden, especially at Kiruna and Gällivare. The reserves at Kiruna are estimated at 1.5 billion tons and at Gällivare at about 200 million tons. Most of the ore is exported to the Ruhr and to Great Britain, although it is used throughout Europe. Another productive district in Sweden is that at Grangesberg in the south central part of the country. Deposits in northern Norway at Sydvaranger and Dunderland have both produced ore and have large reserves; but the long haul to the steelmaking centers, the low grade of the ore (between 36 and 39 per cent iron), and the low phosphorus content have discouraged extensive development.

In the British Isles, the low-grade (25 to 35 per cent iron) deposits of Yorkshire and Northamptonshire furnish a considerable part of the ore available for domestic use. The reserves of this ore are estimated at about 3 billion tons. Other large reserves of low-grade carbonate ores are known in west England and in Wales; the grade is less than 30 per cent iron. The British iron and steel industry has difficulty competing

with higher-grade foreign ores and with the better coal resources of the Continent. The industry is therefore becoming increasingly dependent upon imports.

The Soviet Union contains many large iron ore deposits and has been energetically expanding their production. Probably the best-known of the deposits in the Ural Mountains is that of Magnitnaya near Magnitogorsk. The ores contain an average of between 55 and 65 per cent iron and are low in phosphorus; the reserves are estimated at more than 400 million tons. In the Crimean region on the north shore of the Black Sea, the Kerch Peninsula has long been a producer of low-grade iron ores. The ore mineral is mainly limonite which contains between 38 and 43 per cent iron. The reserves are estimated to be as much as 2 billion tons. A third deposit of similar size and grade is at Krivoi Rog, northeast of Kerch. Other smaller deposits are widely distributed through European Russia.

Deposits of small size or of inferior grades are irregularly worked in Czechoslovakia, Italy, Greece, Albania, Bulgaria, Poland, Switzerland, and Spain.

Asia.—Asia contains large iron ore deposits, although many of them are far from smelters and are relatively undeveloped. The total production of ore is small but is increasing as the local steel-producing centers are expanded. India, with a conservatively estimated reserve of over 12 billion tons of good-grade ore, has some of the largest deposits in the world, mainly in the states of Bihar and Orissa, and in the Bastar District of Madhya Pradesh. Lack of transportation facilities and government-imposed economic restrictions have so far prevented extensive development. The ores are used domestically at the Tatanagar steel works, and very little goes into the export trade. Most of the ores are banded hematites similar to the taconites of the Lake Superior region.

China and Manchuria also contain several large deposits of iron ore. During the Japanese occupation of China, the deposits worked included those on Hainan Island and several magnetite ore bodies along the Yangtze River near Nanking. Low-grade oolitic ores are also mined in the Suanlung district northwest of Peking. The banded ores of Liaoning Province, Manchuria, support a small steel industry. The grade of these ores is only between 30 and 35 per cent iron, but they are said to be very extensive.

Japan has the most completely integrated iron and steel industry in Asia, but is largely dependent upon imported ores. Small magnetite deposits at Kamaishi on Honshu Island are approaching exhaustion, though they are still the largest domestic suppliers of ore. Scattered low-grade deposits of limonite in Hokkaido also yield small tonnages. Limited amounts of titaniferous iron beach sands are used, and residues from the pyrite that is burned in sulphuric acid plants furnish about 1 million tons of sinter annually.

A deposit in the Philippine Islands in the vicinity of Paracale and Jose Pangasinan, on the island of Luzon, annually sends a million or more tons of high-grade ore to Japan. Other magnetite deposits are known in the Philippine Islands but have been little developed. Philippine ore is almost all exported. In the extreme northeast of Mindanao, the Surigao laterite deposits have attracted considerable attention but so far have been uneconomic to mine.

Small deposits of iron ore are worked in Korea, Indochina, Borneo, and the Federation of Malaya. One of the best-known deposits is at Dungan in Malaya, from which about 2 million tons of ore are shipped annually to Japan; this deposit contains an estimated reserve of about 60 million tons. Small deposits of iron ore are known in southern and western Siberia, although few of them are described in available literature, and the reserves and grade are unknown. Probably the largest Siberian deposits are those on the northern slopes of the Altai Mountains near Ilimsk and Abakan. Elsewhere in Asia small deposits in Afghanistan, Turkey, and Arabia, are not at present of great economic value.

WORLD PRODUCTION OF IRON ORE DURING 1950

Source: U.S. Bureau of Mines, *Mineral Facts and Problems*, p. 395 (Washington 1956).

Oceania.—Iron ores are mined in the Middle-back Range, South Australia, and to a much less extent in New South Wales, Queensland, and Tasmania. Deposits of banded ores are known in the Yampi Sound area of Western Australia, but little development work has been done on them. New Zealand has extensive reserves of black sands, much of which is high in titanium and difficult to use in the iron and steel industry. Several small magnetite deposits are known in Indonesia but are of little economic value. Large amounts of laterite in New Caledonia, south-eastern Borneo, and the central Celebes, are not utilized.

Africa.—As Europe and the United States become more and more dependent upon imported iron ores, additional attention is being paid to Africa, especially to the areas most accessible to the coast in the northern and western parts of the

continent. Reserves of more than 500 million tons are estimated to be present in North Africa, largely in Algeria and to a lesser extent in Morocco and Tunisia. The ores range in grade from 45 to 65 per cent iron, and are exported, principally to Germany and England. About 2 million tons of ore are exported annually from the Bomi Hills, Liberia, to the United States. This district contains an estimated reserve of about 30 million tons which average between 60 and 68 per cent iron. Countries that are said to contain deposits of possible economic value include Mauritania, French Guinea, Sierra Leone (Tonkolili District), Nigeria, and Gabon. These deposits are remote from steelmaking centers and will be expensive to explore, to mine, and to transport. Large tonnages of manganiferous iron ores are reported in the Postmasburg district of western South Africa. This district has been best known for its production of manganese, but about 1 billion tons of high-grade iron ores are said to be present. Ores from the Rustenburg district in southwestern Transvaal have been sufficient to maintain a small iron and steel industry at Pretoria. Other deposits in South West Africa, Transvaal, and Natal are known, but so far have proven to be of slight economic value. Large bodies of titaniferous iron ores in the Njombe district of Tanganyika have also remained undeveloped. Other small iron ore bodies exist in the Belgian Congo and in other more remote parts of Africa. Large regions underlain by laterites are also recognized throughout much of tropical Africa.

Total World Reserves.—The total iron ore reserves of the world in 1957 were estimated at about 60 billion tons. This includes ores of all grades but is limited to materials that are economic at the present time. In addition, about 150 billion tons of potential and marginal ores are estimated to exist.

CHARLES F. PARK, JR.

10. MINING AND HANDLING OF IRON ORE.—The geographical locations where the world's iron ore mines have been developed are largely controlled by the cost of assembling raw materials for the steel industry. Because the value of iron ore and coking coal is low in relation to weight, the cost of transportation restricts the distance such materials can be moved economically. As a rule, it is cheaper to move ore to fuel than fuel to ore; hence low-priced coking coal has been the dominant factor in the location of iron and steel industries. The cost of iron delivered at the consuming center and the quality of the ore determine its value, and the grades marketed vary greatly for different localities.

PRODUCING COUNTRIES

The foregoing table lists the production of iron ore by countries producing in excess 200,000 metric tons during 1937, the year of greatest iron ore production prior to World War II:

During 1937, eighteen countries produced in excess of 1,000,000 gross tons each of iron ore, but only seven of these exceeded 5,000,000 tons. The relative importance of these seven producers and their relation to principal importing and exporting countries is portrayed on the preceding chart.

The extensive iron ore exports of France and Sweden move to Europe's steel plants located close to coal. The movement of the iron ores of French Lorraine to the coal fields of the Ruhr and Saar valleys as well as to Belgium and Luxembourg is paralleled in America by the shipments of Lake Superior district iron ores to the coal districts of Pennsylvania, Ohio, Indiana and Illinois. In the latter case there are no international barriers to impede this commerce, and American enterprise has developed the greatest steel producing and manufacturing region in the world.

Grades of Ore Shipped in the United States. The chemical and physical properties of iron ores vary greatly. The presence or absence of desirable elements or objectionable impurities and the physical make-up of ores, as well as their iron content, determine their value at consuming centers.

Phosphorus, sulphur, and silica are the chief impurities found in American ores. When phosphorus is less than .045 per cent, the ores are classed as Bessemer grade. The quantity of permissible phosphorus and silica varies with furnace practices, but usually silica in excess of 8 per cent produces too much slag and is undesirable. Lime, magnesia and, at times, alumina are beneficial as fluxes. Manganese is especially desirable, and if it exceeds 5 per cent, the ore is called manganiferous iron ore and is not classed as iron ore. Manganiferous iron ores come largely from the Lake Superior district,

ing samples at 212° F. to eliminate moisture. Lake Superior ore shipments average more than 10 per cent moisture.

In the Lake Superior district, where freight to market is a major item of cost, the average grade of ore shipped is about 51.5 per cent iron; material containing up to 35 per cent iron is not ore and is called iron formation. Some day much of this material will be concentrated into a high-grade marketable product.

In contrast, in the southeastern district tributary to Birmingham, Alabama, where iron, coal, and limestone occur close together, the ores used, which contain lime and are partly self-fluxing, average only about 36 per cent iron.

Northeastern district shipments from New York, New Jersey, and Pennsylvania average more than 61 per cent iron. Most of this material is a magnetic concentrate or sintered concentrate, produced from low-grade magnetic material containing from 25 per cent to 50 per cent iron as mined. Concentration of such material is necessary in order to yield a high-grade product marketable at consuming centers in competition with Lake Superior or imported ores.

The grades of Western ores as shipped range from about 51 per cent iron for Utah ores to about 55 per cent for California ores.

Lake Superior District.—The Lake Superior district is the greatest iron mining region in the world. It includes the mining localities or ranges tributary to Lake Superior navigation in Minnesota, Wisconsin, and Michigan, and also in Ontario, Canada. These ranges have been developed as follows:

Most of the ore produced in the Lake Superior district moves nearly a thousand miles to market. This is possible because of large-scale, economical operations and cheap water transportation. The average rail haul of ore from mines to Upper Lake ports is about 75 miles. The lake haul is about 750 miles with an additional rail distance of about 150 miles to inland furnaces.

where the Cuyuna range in Minnesota is the principal producer.

Generally, ores high in iron content are preferred, and lower-grade ores in most districts are concentrated to improve their quality. Local conditions determine the grades used.

In marketing iron ores, analyses of iron refer to the quantity of metallic iron in the ores as shipped and not to dry analyses made after dry-

The shipping season is geared to Great Lakes navigation and lasts about seven months each year, depending on weather conditions. Underground mines operate on a 12-month basis and stockpile their winter production. In the open pits stripping operations continue during the freeze-up period, thereby spreading employment and utilizing equipment.

Mining.—There are a wide variety of iron min-

ing methods in use, depending on the shape, size, and location of ore bodies and on the character of the ore and the surrounding rocks. Some ore bodies are close to the surface as on the Mesabi range, and others extend to considerable depths which, on the Gogebic range, exceed 3,000 feet below the surface. Some ores are low grade and require beneficiation before shipment, and others consist of nearly pure iron oxides containing 70 per cent iron.

The mining methods used are those giving greatest safety with maximum efficiency. Where ore bodies dip steeply with small surface exposure, or extend to great depths, underground mining methods are necessary. If the ore is close to the surface with relatively large areas of outcrop, open-pit methods are employed.

In underground mines, top slicing and caving methods are used extensively, especially where the ores are soft. In hard ores, open stope methods are employed, as on the Marquette range. At other places, cut and fill and variations of open stope methods are used.

Mechanization of underground operations is well developed, and innovations are continually being tried out. Because of the great weight or high specific gravity of iron ores in comparison to equivalent volumes of other ores as mined, the equipment used in iron mines is usually of sturdier construction than is generally employed in other mining operations. Machines drill the ore and, after it is blasted, it is moved with mechanical scrapers or loaders to reach shaker conveyors, conveyor belts or electric rail haulage, or a combination of these methods of transportation, to shafts where it is hoisted to the surface and loaded into railway cars or placed on stockpiles.

Open pit mining has its greatest development on the Mesabi range and is described under that heading.

Mesabi Range.—During 1942, 70,280,087 gross tons of iron ore were shipped from the Mesabi range. Production came from 78 open pits and 9 underground mines. This array of operations is condensed into a length of 80 miles and offers an opportunity to view, almost side by side, a wide range in the methods of handling ore.

The largest ore bodies in the Lake Superior district occur on the Mesabi range in iron formation which has a gentle dip, and most of the ore is within 600 feet of the surface. The ore bodies consist of iron oxides formed by oxidation of various iron minerals and by solution and removal of silica from the iron formation, leaving a characteristic, soft, porous ore easy to drill and blast. Previous to mining operations, most of the ore was covered with glacial clays, sands, and gravels that ranged from a few feet to 250 feet in thickness. Part of the ore lies beneath a capping of iron formation overlaid by drift. Where the cost of removing overburden is not excessive, an open pit method is used. The quantity of stripping removed to uncover an ore body during development and operation of an open pit may exceed the tonnage of ore produced. The material stripped consists of glacial drift, iron formation, and lean ores, which are segregated into separate dumps to facilitate possible future utilization. The dumps which have accumulated during the development and shipment of more than a billion tons of open pit ore from the Mesabi range form prominent landmarks near major operations.

Nearly all of the ore in the open pits requires drilling and blasting before it can be handled by power shovels. Standard mobile churn drilling rigs are used for this purpose. In other regions where the ore is harder, closer drilling is required to break the ore, but otherwise the mining methods are essentially the same.

In the open pits the choice of equipment (locomotive haulage, truck or conveyor belt, or a combination of these) and power (steam, electricity, or Diesel) varies with the operation.

Starting in the middle 1930's, locomotive haulage has given way to trucking and belt conveyor installations, and steam locomotives used in the larger pits are being replaced with Diesel electric units, first introduced during 1940.

Power shovels, which previous to 1922 used steam power and operated from railway tracks, have been replaced with smaller, more mobile, and quicker acting electric or Diesel shovels mounted on caterpillar treads.

The evolution in operating methods is illustrated by the changes which have occurred at the Albany mine near Hibbing, Minn. This property is one-half mile long and one-quarter mile wide and its ore body extends onto adjacent property having separate ownership where it is mined by different interests. The Albany mine was opened up in 1902 as a milling pit. The overburden of glacial drift was stripped by steam shovel. An inclined shaft was sunk to the bottom of the ore body from which a system of development drifts (tunnels) extended underneath the ore to be mined. Vertical openings called raises extended from these drifts to surface through the ore. The surface ore was "milled" or shovelled into these raises and drawn off into cars which were hauled by mules to the inclined shaft, and the ore hoisted to the surface. In 1913 the limits of the pit were extended and a narrow gauge railway system was installed. This was changed to a standard gauge railway system in 1924, and the ore was then hauled to the surface by steam locomotives. By 1939, six switchbacks were required to reach the bottom of the pit and much ore was tied up in track benches. A truck haulage system was substituted during 1939, thereby releasing additional ore for mining and obtaining operating economies.

Ore from the property west of the Albany mine, which is part of the same ore body and open pit is handled by trucks which load onto a conveyor belt, carrying the ore from the pit to railway ore cars on the surface.

There is considerable variation in the arrangement of conveyor belts in different pits. At one mine the belt extends from a railway loading pocket on the surface through an underground incline to beneath the ore body. Raises extend from underground feeder belts to the pit bottom with ore delivered to the raises by trucks. At other properties, conveyor belts extend in part through pit walls or are built entirely in the open from pit bottom to railway pockets on the surface.

Several large open pits developed to supply wartime ore requirements use standard railway equipment, but in general the smaller operations use truck or conveyor belt haulage.

The most spectacular mining operation on the Mesabi range is the Hull-Rust-Mahoning open pit at Hibbing. The ore body, parts of which are separately owned and operated, covers an area

of 1,200 acres and is more than 3 miles long with a width ranging up to one-half mile and a depth of about 450 feet. Waste material removed between 1895 and 1945 exceeded 270,000,000 gross tons with ore shipments totaling 383,000,000 gross tons. During the war period, from 1941 through 1945 inclusive, more than 110,000,000 tons of ore were shipped, and each year's shipments exceeded 20,000,000 tons, or, more than 20 per cent of all the iron ore mined from the United States during this period. Haulage of ore mined in the main pit is mostly by rail and during 1944, 40 locomotives were used, of which 13 were steam and 27 were Diesel-electric. Twenty-six power shovels operated, 20 of which were electric and 6 were Diesel, varying in size from 1.5-8 cubic yard dipper capacity. Parts of the ore body have been bottomed, and trucking, called "scramming," was used to deliver ore from power shovels and clean-up jobs to railway cars in the pit. Haulage from several subordinate parts of the eastern end of the main pit was by truck, conveyor belt, and, in one case, a shaft which had ore delivered to it from a conveyor belt serviced by trucks on the pit floor.

When rail haulage is used in the open pits, the ore loaded may go directly into railway ore cars for delivery to shipping ports, or it may require crushing or concentrating by milling methods before shipment. Direct shipping ore is sampled in 5- or 10-car lots as it leaves the mines. Ores requiring crushing, screening, or concentrating are sampled before and after treatment.

Crushing and Screening: Often crushing and screening, or screening alone, is necessary to improve the physical structure of ores as well as to effect some concentration. Lumpy, hard, siliceous material is locally found with good ore, and this lean material can be removed from screens while softer, richer ore breaks to finer sizes and passes through the screens. Products from crushing and screening plants are not classified as concentrates.

Concentration.—Large tonnages of iron-rich material in the iron formation contain too much silica to be used directly in the blast furnace, and such material requires concentration to a purer form. Some lean ores, especially on the western Mesabi range, contain fine, unleached silica grains which can be washed away with a stream of water. These ores are called "wash ores." In other places the silica is in coarser consolidated pieces attached to iron oxides and requires crushing before removal by gravity or other concentration processes. Certain portions of iron formation contain large quantities of finely disseminated and banded magnetite which can be concentrated magnetically after fine grinding. Other portions of iron formation with iron in the ferric state can be roasted to make the iron magnetic, after which magnetic concentration is possible. Various methods of concentration are necessary, depending on the nature of the material to be beneficiated.

The wash ores were the first to be concentrated on the Mesabi range, and the first shipment of concentrates, amounting to 9,816 gross tons, was made in 1907. Since then, jig, high-density or sink-and-float, and magnetic concentrates have been processed. From 1907 until 1945 about 208,000,000 long tons of concentrates were shipped from Minnesota. This material,

by displacing direct shipping ores of richer grade, has conserved the latter for future use. Since 1907 the ratio of concentrates to ore shipments has increased from .03 per cent to more than 22 per cent, and the ratio of total concentrates to total shipments for the period 1907 to 1945 is about 14 per cent. During the war years of 1942-1945, nearly 45 beneficiation plants on the Mesabi range and 5 on the Cuyuna range were in operation, and each year these plants shipped a total of more than 15,000,000 tons of concentrates. The rated capacity of these plants is much larger than this.

An accompanying photograph shows a concentrating plant on the western Mesabi range. This plant, completed in 1910, had shipped more than 55,000,000 tons of concentrates by 1945, and the flow sheet was improved many times during this period.

Metallurgical research by mining companies and other organizations was greatly expanded during and after World War II in order to improve the structure and grade of iron ores being used, as well as to make commercial ore products from lower-grade iron formation. Enormous quantities of such material, containing 30 per cent or more iron, are present in the Lake Superior district. The low value of iron ore, however, requires extremely low-cost concentration processes. The price received for the iron contained in iron ore after it is transported down the Great Lakes is slightly less than one-half cent per pound, of which transportation costs amount to about one-quarter cent per pound of contained iron. There is not much margin for concentration and other expenses, and economic handling on a large scale is required for all operations from mine to furnace.

At the consuming centers, Lake Superior concentrates are in direct competition with North-eastern district concentrates and imported ores. Also the pig iron processed from iron ores in the blast furnaces is in competition with purchased scrap iron for making steel. The importance of scrap iron and the fact that more than 45 per cent of all American steel is now made from scrap were emphasized by the scrap drives during World War II. The increasing use of scrap iron by displacing iron ores is a very important factor in the iron ore trade.

Grading of Ore.—Iron ore shipments from the Lake Superior district are carefully graded to meet strict specifications of the iron trade, and each cargo shipment conforms closely to some guaranteed content of iron, phosphorus, silica, and manganese.

A typical shipment of Mesabi range ore is handled as follows: loaded railway cars from the mine crushing plant or concentrator are sampled in 5- or 10-car lots before being delivered to railway company assembly yards near the mines; there they are grouped into trains of various lengths and hauled by heavy steam locomotives to classification yards near the docks. En route from mine to classification yards the ore cars pass over track scales which record automatically the gross weight of each car. While the ore is in transit, the previously taken samples are analyzed for iron, phosphorus, silica, manganese, and moisture; the ore grader, using these results, determines how the ores should be mixed to yield a cargo of specified grade. Instructions are relayed to the yardmaster at the classifying yards, and, upon arrival

of the ore trains, the cars are regrouped according to the desired block or group of dock pockets for a designated boat. Ore for a single cargo may be sorted from different trains and come from different mines. Additional mixing is sometimes obtained by dumping ore from several cars into the same ore pocket, and such ores are thoroughly mixed as they flow into the boats.

In some districts, domestic and foreign, where ore shipments vary in grade as received at the furnace, bedding plants similar to those used in the copper industry are employed to provide a uniform furnace feed. Blending is controlled by stocking bridges with a belt conveyer feed and a traveling reversing discharge that builds stockpiles in long piles composed of many successive layers of ore. A reclaiming machine spans each stockpile and takes cross-section cuts, which include a portion of each layer of the stockpile. Conveyer belts then carry the ore from bedding plants to furnaces.

Transportation.—Railway equipment, docks, and ore boats in the Lake Superior district are specially designed for large-scale, efficient, rapid ore handling. All railway ore cars are of the steel hopper type, 24 feet long, and dump into alternate pockets on high-level, pocket-type ore loading docks, where 12-foot pockets correspond with 12- or 24-foot spacing of boat hatches. The capacity of ore cars is 50 or 75 long tons; dock pockets hold 250 to 400 tons each; and ore boats carry loads ranging up to 18,000 tons. The central portion of these vessels is cargo space, with crew quarters, engines, and fuel grouped together in bow and stern.

At upper lake ports ore from the ore docks flows by gravity from ore pockets through long steel spouts into the holds of the boats, and the loading time of a boat is about 4 hours. The record loading time for a cargo of 12,817 tons is 16.5 minutes. Unloading at lower lake ports is done rapidly by means of huge clamshell buckets of 9-ton capacity or by means of giant electrically driven Hulett unloaders with maximum bucket capacities of 20 tons. There are about 300 ore boats in service, with a carrying capacity per trip of nearly 3,000,000 long tons. An ore boat can make a round trip in about a week unless coal is carried on the return voyage, in which event the round trip may take as long as 10 days. Ore from lower lake ports goes either directly to consuming furnaces or to stockpiles at the docks.

Ranges in Ontario, Canada.—The Atikokan and Michipicoten ranges in Ontario, Canada, occur within the Lake Superior district, and their production is shipped via Lake Superior. Much of this ore is consigned to furnaces in the United States.

The first ore shipment from the Atikokan range was made during 1944 after a large river was diverted and a lake pumped out to uncover ore which lay beneath 50 to 150 feet of water and considerable mud, clay, and gravel. This development, now an open pit power shovel and trucking operation, will eventually require underground mining methods. The ore is shipped by rail about 140 miles eastward to Port Arthur on Lake Superior, where a high-level, pocket-type dock was completed during 1945.

The Michipicoten ore is largely an iron carbonate. After mining, which includes open pit as well as underground operations, the ore is crushed and roasted to drive off carbon dioxide.

This calcined product is then sintered and shipped by rail to a Michipicoten harbor. Port facilities include a 12,000-ton loading bin with a conveyer belt system for loading ore boats.

Southeastern District.—Iron mining in the Southeastern district is centered around Birmingham, Ala., where the advantage of the coexistence of iron ore, coal, and limestone offsets the lower quality of the ores used.

The ores found near Birmingham, called Clinton ores, are red hematites of bedded sedimentary origin. They dip about 20° from the horizontal, but flatten to around 10° in depth. Mining, which started in open pits in soft leached ore, is now confined mainly to underground operations in hard ore. Inclined shafts called slopes follow down just beneath the ore seams, and in some places these haulage ways extend for a mile or more down the dip. Levels extend out from the slopes, and the ore is mined in open stopes, excavated working places where pillars are left to support the roof or hanging wall. After drilling and blasting, the ore is scraped with mechanical loaders into ore cars and transported by rail to loading pockets at the main slopes. The ore flows into skip cars and, after being hoisted to the surface, is crushed, screened, and sized before being shipped to nearby furnaces. The ores as mined average 35 to 37 per cent iron, with 0.2 to 0.4 per cent phosphorus, and in large part contain enough lime to be self-fluxing.

Some Clinton ore is mined on a smaller scale in northeastern Alabama, Georgia, Tennessee, and Virginia.

In addition, brown ores, consisting principally of limonite associated with clay, sand, and gravel, are mined in open pits. These ores require washing and screening before shipment. The largest production of this type of ore comes from the Russellville area of northwestern Alabama, with additional shipments from Kentucky and Tennessee.

Northeastern District.—The Northeastern district includes producing mines in New York, New Jersey, and Pennsylvania. The ore consists of magnetite in various amounts associated with ancient banded rocks. In several places the iron occurs as nonmagnetic hematite or martite as well as magnetite. Impurities include phosphorus, sulphur, titanium, and silica. Some of the ore is rich enough for direct shipment as premium lump ore, but most of it, as mined, ranges from 25 to about 50 per cent iron and requires concentration. Concentration plants in service at the end of World War II had a rated annual production capacity in excess of 5,000,000 long tons of concentrate which should average better than 60 per cent iron.

New York.—Mining operations are now centered in the Adirondack area of northeastern New York, where the entire iron mining practice has been renovated and expanded since 1937.

Underground mines are located near Port Henry and Lyon Mountain, where the magnetite ore horizon dips at variable angles. Inclined shafts extend downward, usually just beneath the ore. Where the ore horizon is steep enough for the ore to run by gravity, shrinkage stopes (an overhead mining method in which sufficient broken ore is left in the stope to provide wall support and to act as a working platform) are used. Where the ore lies flatter, the ore is mined in open stopes, and mechanical scrapers

move it into ore cars on tramming levels where it is hauled by storage battery locomotives to the inclined hoisting shafts. The ores, as mined, range from 25-50 per cent iron, which is increased by magnetic concentration to better than 63 per cent iron. Concentrates are sintered before shipment to produce a suitable agglomerate for furnace charging.

Open pit and, in part, underground mining methods are employed in the western Adirondacks at two properties developed during World War II. Magnetic sintered concentrates containing in excess of 62 per cent iron are concentrated from crude ores ranging from 25-42 per cent iron. At one property sulphur in the form of pyrrhotite is concentrated with the magnetite, but this sulphur is eliminated by roasting during the sintering operation.

New Jersey.—Iron mining in New Jersey is now mostly in the Mount Hope-Dover area where the crude ore usually ranges from 25-50 per cent iron. Some of the ore contains more than 60 per cent iron and is shipped as premium lump. The magnetite-rich ore zones or lenses dip steeply and also trend or pitch northeastward in depth. Shafts either follow the dip of the ore bodies or are vertical with crosscuts driven to reach the ore. Mining is by shrinkage stoping.

Magnetic concentration raises the shipping grade of ore to 60 per cent or more in iron content. In one case where some hematite occurs with the magnetite, the hematite is recovered on vibrating tables after magnetic separation of the magnetite.

Pennsylvania.—Principal iron ore production in Pennsylvania comes from a combined open pit and underground operation near Cornwall. The crude ore contains about 35-45 per cent iron, 0.1-0.6 per cent phosphorus, 0.5-2.0 per cent sulphur and 0.2-1.0 per cent copper.

The ore body pitches or extends downward at about 30°, and the upper portion of it is mined as an open pit which is nearly a mile long, 1,000 feet wide and 600 feet deep. The open pit ore is churn-drilled and blasted in benches ahead of power shovels which load into trucks. These dump into an inclined skip which delivers ore to a crushing plant from which it is transported by rail to the concentrator.

Open stope, shrinkage stope, and block caving (described under *Western District* below) mining methods are used underground, and ore is hauled in tram cars to an inclined shaft for hoisting to surface.

The ore requires crushing and fine grinding, after which magnetic concentration, jigging, and tabling are necessary to yield a magnetic concentrate containing more than 55 per cent iron. This concentrate is sintered before shipment. Copper is recovered as a byproduct during concentration.

Western District.—Most western iron ores are magnetites, or mixtures of hematite and magnetite, mined by open pit methods.

Wyoming.—Hematite associated with iron formation of Lake Superior type is mined by underground methods near Sunrise, Wyoming. This ore body was originally mined as an open pit, but all mining is now underground where block caving is used very successfully. After extensive development of a level, the ore to be caved is undercut and the weight of the overlying rocks crushes the ore. It is then drawn off through chutes into mine cars. This mining method re-

quires careful supervision of the manner of drawing, in order to prevent dilution of the ore with waste rock. The Sunrise ore is shipped by rail to Pueblo, Colorado.

Utah.—The ore bodies being mined in Utah have very little overburden and are well suited for mining by open pit methods. The first Utah iron mines were developed with tunnels driven into hillsides beneath the ore. The tunnels were connected to open pits or "glory holes" by vertical openings. The ore was milled to these openings and trammed on tunnel levels to railway shipping pockets. All mining is now by open pit methods at Iron Mountain, where the ore is loaded by electric power shovels into trucks which dump into a crushing and screening plant from which the ore flows by gravity into railway cars for shipment to furnaces near Provo, Utah.

During World War II, other open pit operations at Iron Mountain and Iron Springs shipped ore to Pueblo, Colorado and Fontana, California.

California and New Mexico.—Open pit mines in California and near Hanover in New Mexico use power-shovel, trucking operations.

Missouri.—Principal production of iron ore in Missouri comes from Iron Mountain where mining started in an open pit; it is now an underground operation. The ore is concentrated by jigging and tabling, and the product, containing about 55 per cent iron, is shipped to Granite City, Illinois.

Numerous small brown ore pits, mostly in southeastern Missouri, produce ore as market conditions warrant.

Texas.—Open pit mining of northeastern Texas brown iron ores started during World War II. The crude ore contains about 27-42 per cent iron which is concentrated to about 53 per cent iron. Peacetime mining operations depend largely on local consumption.

FOREIGN COUNTRIES

The only countries besides the United States which have adequate coking coal reserves together with iron ore supplies, domestic or imported, to support major iron and steel industries are (1) the Soviet Union; (2) France with Germany; (3) Great Britain; and (4) possibly India and Australia. Major sources of iron ore used by these countries are reviewed below.

Soviet Union.—The chief Russian iron mines are located near Krivoi Rog in the Ukraine and at Magnitogorsk in the Ural Mountains. The Krivoi Rog area produces about 60 per cent of Russia's iron ore from underground mines where sublevel stoping or caving methods are used to mine lens-shaped ore bodies more than 2,000 feet long and equally deep. The ore averages about 57 per cent iron, 8 per cent silica, and 0.05 per cent phosphorus, and, together with coal from the Donets Basin, forms the nucleus of an important iron and steel industry.

The Magnitogorsk ore ranges from 45-60 per cent iron and is mined by open pit methods. This ore is shipped eastward by rail nearly 1,500 miles to the Kuznetsk steel plant in the Kuzbas Basin coal fields, and coal is carried on the return trip to a steel plant near Magnitogorsk. These steel plants played an important part in Russia's war effort after the Ukraine was overrun by the Germans during 1941.

France.—France's production of iron ore is usually second only to that of the United States.

The steel industry of France is concentrated in the Lorraine Basin of northeastern France where large deposits of minette iron ore of sedimentary origin occur. Minor quantities of ore extend into nearby Luxembourg and Belgium. The minette ores resemble the Clinton ores of the Birmingham district in America and, as mined, most of the ore averages about 30 per cent iron, 0.7-0.9 per cent phosphorus, 12-20 per cent lime, and 5-10 per cent silica. Some siliceous phases contain from 12-25 per cent silica. The ore beds are flat-lying and are mined underground from vertical shafts. A retreating room and pillar mining method is used, and pillars are left to support the surface. Mechanical loaders, conveyor belts, and shaker conveyors are used in some of the mines.

Minette ores are exported to the coal fields of the Ruhr and Saar valleys as well as to Belgium and Luxembourg, and coal is imported from these areas for the French iron and steel industry.

Germany.—Previous to 1918, while Germany controlled Lorraine, the minette ores supplied most of Germany's iron ore requirements. With the loss of Lorraine after World War I, domestic iron ore deposits were developed which contain only about 30 per cent iron with 25 per cent silica. These lean ore bodies were mined chiefly by underground methods, with shafts ranging to 2,000 feet in depth. Production supplied only about 13 per cent of Germany's metallic iron requirements, and she was forced to import ores, chiefly from France and Sweden.

Sweden.—The major Swedish iron production is from the Kirunavaara open pit in northern Sweden or Lapland, where ore is loaded by electric power shovels into mine cars for delivery to a crusher in the pit and transported in 35-ton bottom dump cars. These are hauled by electric locomotives to Lulea on the Baltic or to Narvik, Norway for export. The ore docks at Narvik and Lulea resemble Lake Superior type docks, without storage pockets.

Other deposits in Lapland and near Grangesberg in southern Sweden are mined underground by shrinkage stoping method; these ores are crushed and concentrated to yield a high-grade, low-phosphorus product. Southern ores shipped from the port of Oxelösund are loaded on steamers either by grab buckets of 17-ton capacity or by conveyor belts.

Export ore contains about 60-62 per cent iron and 0.15-2.76 per cent phosphorus and, previous to World War II, was shipped principally to Germany and Great Britain.

Great Britain.—The iron mines in Great Britain are located chiefly in the Middlesborough, Northampton, Leicester, Frodingham, and Cleveland mining districts. The ore occurs in flat-lying sedimentary beds which are mined largely in open pits. A maximum 85 feet of cover is removed to expose ore ranging from 6-30 feet in thickness. Overburden is stripped by power shovel, chain bucket excavators, or by dragline. The ores contain only about 30 per cent iron and 0.3-0.7 per cent phosphorus. Lime and silica vary for different deposits, and bedding plants similar to those used in America are in use at some furnaces to provide a uniform furnace feed. It is necessary to import ores of better grade for use in the British iron and steel industry.

Newfoundland.—High phosphorus, Wabana

ores mined from Bell Island, Newfoundland, are exported to Europe as well as being used at furnaces in Nova Scotia, Canada. These deposits are close to American markets, but American practice has not been designed to use these high-phosphorus ores.

The Wabana ores, of sedimentary origin, occur in several beds interbedded with other sediments which dip away from Belle Island beneath the ocean bottom. Inclined double shafts follow down the dip of the beds, and mining of the ore has progressed from two to three miles beyond the shoreline at depths of 1,600 feet below sea level, equivalent to 1,300 feet below sea bottom. A room and pillar mining method is used, and from 40-50 per cent of the ore is left as pillars. Mechanical loaders, scrapers, and power shovels are used underground to load cars. The ore is crushed on the surface and moved two miles to shipping port. The shipping grade of ore averages about 51 per cent iron, 11.5 per cent silica, and 0.92 per cent phosphorus.

Other Countries.—Iron mining in other parts of the world is mostly by open pit methods. There is a wide range in the extent of mechanization of mining operations in foreign countries. In the open pit at Kirunavaara, Sweden, power shovels and mine cars are of American make, and this mining operation compares favorably with the best American practice. In contrast, in densely populated India where labor is cheap, iron ore is carried in baskets by natives from open cut working faces to railway cars.

11. IRON AND STEEL, Metallography of.—Metallography deals with the crystal structure of metals and alloys, with the effect of the composition and treatment of the alloy on the structure, and, in turn, with the way the structure affects the properties. Metals are made up of crystals similar in appearance to the crystals in a polished piece of granite. Metal crystals may be very soft and ductile or they may be very hard and brittle; they may be very coarse or very fine. The properties of an alloy may depend as much on the size, shape, and distribution of its various crystals as on the composition. The crystal structures of iron and steel are of remarkable variety, enabling metallographic study to reveal a surprising amount of information about the

composition and treatment of any particular specimen. These structures suggest how defects present may be eliminated, how desired qualities may be attained, and how new or improved alloys may be produced. Metallography is one of the most important means of production control, inspection, and research of iron and steel.

Visual Examination.—Significant structural features in iron and steel articles are frequently large enough to be observed with the unaided eye. For example, the fracture of a broken specimen may indicate whether the structure is coarse or fine, uniform or heterogeneous. The more usual procedure preparatory to visual examination is to etch deeply a section cut through the specimen with a hot solution containing one volume of water to one volume of concentrated hydrochloric acid for about 15 minutes. The etched surface will then clearly reveal the degree of fineness and uniformity of the structure, the rolling direction of a rolled article, the presence of porosity and unsoundness in a casting and cracks.

Figs. 1 and 2 illustrate typical structures of deep etched steel as they appear when viewed with the unaided eye or as magnified somewhat with a hand lens. Fig. 1 shows the dendritic or pine tree crystals which form in cast steel. The elongated crystals at the left are at the surface of the casting and the crystals at the right, of uniform diameter in all directions, are at the interior of the casting. Fig. 2 shows a section through an electric-arc weld on a steel plate. The humped region at the top is the fused-in metal from the melted electrode; directly underneath are various layers of the plate in which the structure was changed by the welding heat; beneath is the unchanged structure of the plate.

An interesting example of visual examination is the detection of cracks in steel by means of magnetic powder. The steel specimen is magnetized and fine magnetic powder is sprinkled over the surface, or the specimen is immersed in kerosene in which the magnetic powder is suspended. The magnetic powder will gather at any crack that may be present in the magnetized specimen, bridging the crack and thus making it clearly visible.

Microscopic Examination.—For revealing the finer details of the structure of iron and steel, the microscope must be used. In most cases the crystalline constituents are of such a size that their significant features can be revealed at the moderate magnification of X100. Frequently a higher magnification such as X500 is necessary. The limit of useful magnification of the optical microscope is about X2000. The newly invented electron microscope has been applied to the study of metals. In this way magnifications as high as X20,000 and higher have been attained. On a still finer scale, the positions of the atoms in the unit cells or lattices of which crystals are composed can be determined by X-ray diffraction analysis. In iron these unit cells are of the cubic type. At temperatures below 1670° F. for pure iron, the lattice is *body* centered cubic, known as *alpha*, or alpha iron, an iron atom being present at each corner of the cube and in the center of the cube. On heating pure iron above 1670°, the lattice changes to *face* centered cubic, known as *gamma*, or gamma iron, an iron atom being present at each corner of the cube and in the center of each face of the cube. At 2552° F., the lattice again

changes to *body* centered cubic, known as *delta* or delta iron. The two types of cubic lattice in iron are illustrated in Fig. 3. Alpha iron can dissolve up to 0.035 per cent carbon and larger amounts of other alloying elements, and the resulting solid solution is called *ferrite*; gamma iron can dissolve up to 1.7 per cent carbon and varying amounts of other alloying elements, and the resulting solid solution is called *austenite*. The amount of the elements dissolved in the alpha iron and gamma iron depends upon the maximum temperature attained and the time during which the iron is at this temperature. The amount of the elements retained in the dissolved state in the solid iron depends upon the cooling rate from the maximum temperature, any subsequent reheating and cooling, and the preferential effect of one element upon the solubility in iron of the other elements. The length of a side of the body centered unit cube of iron (as illustrated in Fig. 3) is approximately 1/100 of a millionth of an inch.

FIG. 3. Constitutional diagram of iron and iron carbide.

Before a specimen can be examined under the microscope the surface to be viewed must be properly prepared. The usual method is to grind and polish a section cut through the specimen. The polished surface of the specimen must usually also be etched to reveal the crystal structure fully. Metals are opaque so that you cannot see through them by transmitted light as in the case of some minerals; they have to be observed by reflected light. In grinding and polishing, a convenient sized specimen having one side about ½ square inch in area is first ground on a coarse emery wheel, then on finer emery papers, and finally polished with polishing cloth mounted on a wheel. In this final stage a very fine abrasive like alumina suspended in water is applied to the polishing cloth. The polishing action should be a cutting action as much as possible, and also should be mild, so as not to flow and smear metal over the surface. Many structural features may be observed in the as-polished condition, but usually the specimen is also etched. Light etching as with 2 per cent nitric acid in alcohol for about 15 seconds is usually sufficient. After etching, the specimen must be rinsed, washed in alcohol, and carefully dried. Metallography is a fine art, and beautiful results can be obtained when the structures are properly revealed.

Figs. 4 and 5 show the structures, as magnified by the microscope, of the same specimens as are illustrated in Figs. 1 and 2 without appreciable magnification. Fig. 4 shows the coarse, angular type of structure which may appear in steel in the as-cast state. Fig. 5 illustrates the structures at the weld of Fig. 2. In Fig. 5 the fused-in metal of the weld is at the left and

the first layer beneath the fused-in metal, illustrated in Fig. 2, is at the right. The dark, vertical, diamond-shaped impressions in Fig. 5 were made for testing the hardness, the smaller the impression produced by the test load, the greater the increase in hardness. The fused-in metal at the left of Fig. 5 is softer (larger impression); the metal at the layer at the right is harder (smaller impression).

Fig. 6 illustrates coarse- and fine-grained structures in steel. Specimens *A* and *B* were steels of similar composition heated in the same way for 8 hours at 1700° F. in a carburizing compound, consisting mainly of powdered coke. Steel *A* became coarse; steel *B* remained fine. The fine-grained type of steel can be produced by adding to the molten steel about 2 pounds of aluminum per ton of steel. The fine-grained type

FIG. 9.

of steel is tougher than the coarse-grained type, but both types have advantages for certain purposes.

In Fig. 7, *A* is typical of the grain structure of low carbon iron or ferrite; Fig. 7, *B* shows the same spot as 7, *A* after the sample was cold worked. The parallel lines in Fig. 7, *B* are slip lines which formed as a result of the cold working. The effect of cold work is to harden the iron. With proper technique the cubic crystal habit of ferrite grains may be revealed. This is illustrated in Fig. 8.

Constitution of Iron Carbon Alloys.—

Low carbon iron, steel, and cast iron all belong to the series of alloys of iron and carbon. One of the best ways of indicating fundamental differences among these alloys is the constitution diagram of the iron-carbon alloys. In Fig. 9 may be seen the whole series of alloys of iron and carbon; from carbon-free iron at the left, to alloys containing 6.7 per cent carbon at the

right. The effect of temperature on these alloys from 0° F. to above their melting point is also indicated.

Steels are the most important iron-carbon alloys. The steels range in carbon content from about 0.1 per cent carbon to about 1.5 per cent carbon. Beyond this carbon content, from about 2 per cent carbon to about 4.5 per cent carbon, are the alloys known as the cast irons.

It may be seen in the diagram of Fig. 9 that as the carbon content of the alloys goes up, the solidification temperature goes down. Thus pure iron completely solidifies at the very high temperature of about 2800° F. But steels completely solidify at lower temperatures, as indicated by the boundary line *JE*. Above the line *JE* some "liquid" is present along with the "solid austenite," whereas below the line *JE*, only solid austenite is present. At the point *E* an alloy of 1.7 per cent carbon completely solidifies at about 2100° F. All alloys higher than this in carbon (including the cast irons) completely solidify at about 2100° F., along the line *ECF*. The composition at the point *C* on this line is the alloy of iron and carbon with the lowest melting point. This is called the eutectic composition, the word *eutectic* signifying lowest melting point. The cast irons are close to the eutectic in composition, and their consequent low melting point is one of the main reasons why cast irons are used. The cast irons are much more easily melted than the low-carbon steels; they can be made very fluid and, therefore, make good castings.

Carbon is the hardening constituent in steel. In slowly cooled steel, carbon is present as a hard, iron-carbon compound (iron carbide) called *cementite*. In steels with less than about 0.8 per cent carbon, the carbon is incorporated in the constituent called *pearlite*, which consists of alternate lamellae of ferrite and cementite. In slowly cooled steels with less than 0.8 per cent carbon, the constituents present are ferrite and pearlite as indicated in Fig. 9 in the region below the line *PS*. In slowly cooled steels containing more than 0.8 per cent carbon, ferrite is no longer present; in these alloys, the carbon up to 0.8 per cent carbon is present as the cementite lamellae in pearlite; the rest of the carbon forms cementite boundaries about the pearlite grains.

As indicated in Fig. 10, low-carbon steel consists mainly of ferrite with some pearlite. The ferrite is the light constituent and the pearlite, the dark constituent. As the carbon content increases, the amount of pearlite increases and the amount of ferrite decreases. In slowly cooled steel with about 0.8 per cent carbon, the structure consists entirely of pearlite. Obviously, pearlite has a composition of approximately 0.8 per cent carbon.

In slowly cooled steels which have a carbon content greater than that of pearlite, cementite (iron carbide) forms boundaries about the grains of pearlite. This is illustrated in Fig. 11, *A*. These rather thin cementite boundaries (the cementite is light colored) may be seen in about the center of Fig. 11, *A*, where several boundaries join. Fig. 11, *A* also illustrates the details of the structure of pearlite. The alternate lamellae in pearlite produce a fingerprint pattern which is easily recognized when viewed at the proper magnification. In Fig. 11, *A*, in which the fingerprint structure is clearly visible, the magnification is X500. In Fig. 10, at X100, the magnification is too low to resolve the fingerprint pattern of the

- 12 Structure of quench-hardened steel X500. This acicular or needlelike structure which forms in quench-hardened steel is called "martensite."
- 13 Structure of white cast iron X500. The white areas are massive cementite, the dark areas are pearlite.
- 14 Structure of gray cast iron X100. The large black plates are flakes of graphite; the groundmass is composed of pearlite and some ferrite.
- 15 Structure of malleable cast iron X100. The black patches are graphite nests; the groundmass is ferrite.
- 16 Structure of wrought iron X100. The matrix is ferrite. The dark parallel streaks are slag.

pearlite.

The steel of Fig. 11, *B* has about the same carbon content as Fig. 11, *A*. By a special heat treatment the cementite (iron carbide) was coalesced into globules to form "spheroidized cementite." The structure consists of a ferrite groundmass containing the cementite globules. A steel having such a structure is considerably softer than a steel of the same composition in which the structure consists of pearlite and cementite boundaries as in Fig. 11, *A*.

Hardening of Steel.—Many steels for engineering structures are used in the slowly cooled (air-cooled) condition, and these steels owe much of their hardness and strength to the presence of pearlite, as has been indicated above. However, a much higher order of hardness is obtainable if the steel is cooled very rapidly from above its critical temperature, instead of being allowed to cool slowly. Such rapid cooling from above the critical temperature, as by quenching the hot steel in cold water, is what is meant by "hardening." Reference to Fig. 9 of the iron-carbon constitution diagram will be helpful in explaining what takes place in the quench hardening of steel.

As previously described, iron exists in two forms, as ferrite below the critical temperature and as austenite above the critical temperature. The critical temperatures are indicated by the lines *PSK* and *GSK* in Fig. 9. Above the line *GSK* the iron is present as austenite; below the line *PSK* it is present as ferrite; between *PS* and *GS* there is a mixture of ferrite and austenite, as indicated by the arrow in the diagram. Hardening can occur mainly because the austenitic form of iron can hold a large amount of carbon in solution, whereas ferrite can hold only a minute amount of carbon in solution. It is indicated in Fig. 9 that austenite can hold as much as 1.7 per cent carbon in solution whereas ferrite can hold only about 0.035 per cent. If a steel is cooled slowly from above the critical temperature, the carbon can separate when the critical temperature is traversed, and the austenite changes to ferrite and cementite. But when the steel is very rapidly cooled through the critical temperature, there is not time enough for the cementite to separate. The austenite transforms to ferrite but the cementite does not separate. The bulk of the cementite is, therefore, retained in the ferrite in supersaturated solution, although some of the cementite precipitates as an extremely fine (submicroscopic) dispersion. The extreme hardness of quench-hardened steel may be attributed to the supersaturated solution and fine dispersion of the cementite in the ferrite.

Fig. 12 shows the acicular or needlelike constituent which forms in steel when hardened by quenching from above the critical temperature. This constituent is called *martensite*. Martensite is extremely hard and it is the structure desired in steel for metal-cutting tools, files, and cutlery. Extreme hardness generally denotes brittleness. Thus as-quenched martensite may be too brittle. Quench-hardened steel can be made tougher and less brittle by heating it somewhat after quenching. Such heating is called tempering. The higher the tempering temperature, the softer and less brittle and the tougher is the steel. The quenched and tempered structure, is therefore the commonly sought structure in heat-treated steel. The tempering

temperature is determined by the hardness required in the finished article. For extreme hardness the tempering temperature may be about 400° F.; for great toughness the tempering temperature may be as high as 1200° F. During tempering the cementite separates from the martensite. At the higher tempering temperatures the cementite coalesces into particles large enough to be resolved in the microscope. After tempering at about 1200° F., the cementite appears as the good-sized globules of spheroidized cementite illustrated in Fig. 11, *B*.

Effect of Alloying Elements.—A word may be said about the effect of the alloying elements in steel, such as nickel, chromium, molybdenum, vanadium, and others. The alloying elements may be present in solution in the ferrite, and some of them may also be combined with carbon and one another to form carbides. In this way they may exert a considerable strengthening effect. However, the main effect of the alloying elements is in slowing down the rate at which austenite transforms to ferrite and cementite during cooling through the critical temperature region. As a result, instead of requiring extremely fast cooling from above the critical temperature to produce martensite as in plain carbon steel, very much slower cooling from above the critical temperature is sufficient to produce martensite in alloy steel.

The importance of this will be clear from the following example. A 1-inch diameter bar of plain carbon steel, which is heated to a temperature above the critical temperature and then immediately quenched in cold water, will cool rapidly enough to form martensite, only at the surface. Martensite will be formed only to a depth of about $\frac{1}{8}$ inch. In the interior of the plain carbon steel bar the rate of cooling even in cold water will be too slow to form martensite. On the other hand, in a 1-inch bar of alloy steel similarly quenched or even more slowly cooled, as by quenching in oil, the martensite will form throughout the bar. Accordingly, the main effect of the alloying elements is to make possible very deep hardening of large sections, and likewise the attainment in large sections of the desired quenched-and-tempered tough structures. In thin sections, as in wire, just as high strength and toughness can be obtained with plain carbon steel as with many alloy steels.

Cast Iron.—The place of the cast irons in the iron-carbon constitution diagram of Fig. 9 has already been discussed. In these high carbon alloys the carbon may be present as cementite or as graphite.

Cast iron in which all of the carbon is present as cementite is called white cast iron. It contains about 3 per cent carbon and about 0.5 per cent silicon. The structure of white cast iron is illustrated in Fig. 13. The large white areas are massive cementite and the dark areas are pearlite. Because so much of the very hard constituent cementite is present, white cast iron is extremely hard and brittle. It is used for such purposes as grinding balls in ball mills and chilled rolls for rolling metal.

In gray cast iron most of the carbon is present as flakes of graphite. The structure of gray cast iron is illustrated in Fig. 14. For the carbon to be present in the form of graphite instead of cementite, the alloy must contain a good deal of silicon, which promotes graphitization. Ordinary gray cast iron contains about 3.5 per

cent carbon and about 1.75 per cent silicon. The groundmass structure of gray cast iron is pearlite and ferrite and hence is quite tough, but it is broken up by graphite flakes so that the iron is brittle. The graphite in gray cast iron improves its machinability, however, and castings of this material find applications in automotive cylinder blocks and pistons, stoves, radiators, and many other products.

Another variety of cast iron is called malleable iron, the structure of which is illustrated in Fig. 15. This contains about 2.5 per cent carbon and about 1.25 per cent silicon. The silicon content is low enough for the alloy to solidify as white cast iron, but there is enough silicon present to promote graphitization in the subsequent heating or annealing process to which this type of casting is subjected. This malleablizing annealing is done in two stages, first by heating at about 1600°F. in order to graphitize the massive cementite, and then by heating at about 1325°F. in order to graphitize the last remnants of pearlitic cementite. In malleable iron the graphite which forms during the malleablizing annealing is present as rounded nests (Fig. 15), rather than as elongated, sharp flakes, as in gray cast iron (Fig. 14). Because of this, and because the matrix of malleable iron is composed entirely of soft ferrite, malleable iron has considerable toughness and is not brittle, as is gray cast iron.

Wrought Iron.—Unlike cast iron, which is a high-carbon cast material, wrought iron is a substantially carbon-free forged or rolled material. It is distinguished by the fact that during its manufacture slag is incorporated in its structure. The elongated slag streaks in a wrought iron bar are illustrated in Fig. 16. These streaks impart a fibrousness to the structure.

12. IRON AND STEEL INDUSTRY IN THE WESTERN HEMISPHERE.

The iron and steel industry has developed over a period of three centuries in the United States, about two centuries in Canada, since the 1880's in Mexico, and mainly after World War II in South America. In the 1950's the industry in the United States well supplied the domestic demand for iron and steel. Of the other countries in the Western Hemisphere, Canada was best able to meet its demand.

Although the Western Hemisphere contains some of the principal iron ore and coal reserves of the world, those mined extensively before World War II were all located in the United States and Canada. The postwar development of iron ore deposits in South America stimulated the expansion of the Latin American iron and steel industry and assured the United States of additional sources of iron ore.

The following sections describe the iron and steel industry in the United States, Canada, Mex-

ico, Argentina, Brazil, Chile, Colombia, Peru, and Venezuela.

UNITED STATES

The basic importance of the iron and steel industry in the economy and welfare of the United States may be glimpsed from a few facts. Iron and steel are the most widely used of all the metallic materials and are also the most necessary in modern civilization. The 1954 United States raw steel output of 88,311,652 net tons was about 36 per cent of the world output of 246,292,759 net tons, and the country's estimated per capita output for the year was 1,097 pounds.

Nearly 40 per cent of all the jobs in the manufacturing industries of the United States are created by the domestic manufacture and industrial uses of iron and steel. This industry is so intimately associated with the national economy that it is difficult to name one item of food, clothing, shelter, convenience, or luxury that does not contain iron or steel or is not made, transported, or consumed with the aid of iron or steel equipment. Consequently, the activity of the iron and steel industry is a basic indicator of the economic health of the country.

In 1954 it was estimated that an investment of more than \$75,000 in construction and equipment was required to make a job for just one man in the iron and steel industry. That investment is one measure of the huge scale of operations, a scale which enables the industry to produce iron and steel abundantly and at prices that permit their use in 200,000 products. The estimated price of steel in a few of these products, together with their estimated retail price, is shown in Table 1.

Table 1—RETAIL PRICE AND PRICE OF STEEL FOR SELECTED PRODUCTS

(Estimated as of March 1953)

Product	Estimated retail price of product	Estimated price of steel in product
Automobile	\$1,984.00	\$225.00
Baby carriage	29.95	2.25
Electric iron	11.95	.47
Electric shaver	27.50	.10
Range	370.00	13.80
Refrigerator	350.00	13.56
Toaster	21.95	.72
Typewriter	165.00	3.85
Vacuum cleaner	89.95	1.60

The importance of iron and steel in the growth of the United States is evident in the founding and development of the industry during the colonial period and in the expansion of the industry since the mid-19th century. Succeeding sections describe (1) the colonial iron industry, (2) the colonial steel industry, and (3) the expansion of the industry from 1783 to 1864. The latter year marks the beginning of large-scale steel manufacture by the Bessemer converter in the United States. The fourth and final section, covering the period since 1865, treats the modern era of the industry, during which steel first became available in large quantities at low cost, and thousands of varieties of iron and steel were developed for particular uses.

Colonial Iron Industry.—A combination of unusual circumstances attended the founding of the iron and steel industry in what is now the United States. Workable low-grade deposits of iron ore existed along the Atlantic seaboard in practically all of the colonies. Also abundant were virgin forests and easily dammed streams; the former furnished fuel for the furnaces, and the lat-

Map 1. Beginnings of the Southern iron industry.

ter water power for the air blast and forge hammers. Slow communications with Europe and restrictive English laws and trade practices encouraged the colonists to work these deposits and to make iron products for local consumption.

The English Parliament might have severely handicapped the development of the colonial iron industry if timber had been plentiful in England or if iron smelting had been more advanced technically. In the 17th century charcoal was the only fuel used in blast furnaces and forges, and wood in the form of charcoal was being consumed more rapidly than it could be grown in England. The shortage of timber alarmed the English government, which was trying to maintain naval supremacy and expand trade. Consequently, English ironworks were prohibited from using timber suitable for shipbuilding within 14 miles of the sea or any navigable river. England therefore became an importer as well as a producer of iron. Had English ironworkers known that the readily available coal or coke could be used to smelt iron ore, the iron industry in colonial America might not have been established in the 17th century. Since it was English colonial trade policy to import raw materials from the colonies and export finished products, it is very probable that English ironworks would have supplied the American colonies with iron and iron products.

17th Century.—Although iron ore was discovered on an island off the shore of North Carolina in 1585, no colonial deposit was worked until 1608, when ore discovered in the previous year along the James River, Virginia, was shipped by the East India Company to England. For the first shipment of 17 tons the colonists received

£68. By 1619 the Society of Southampton Hundred (Southampton Adventurers) planned to build three ironworks in Virginia, under patents granted by the Virginia Company of London (London Company), to smelt the ore that occurred in ponds and bogs. Falling Creek, near the present city of Richmond (see Map 1), was intended to be the site of the first of these works. It has been reported that a furnace was built in 1622, that on the day it was scheduled to begin operations Chief Opechancanough and his braves massacred the settlement of 348 (save for a boy who escaped to Jamestown), and that the society abandoned its plans to build the other works. Examination of the reported furnace site and other possible sites and of contemporary and later documents has not conclusively indicated the existence of a furnace.

In June 1641, the General Court of Massachusetts Bay Colony offered "encouragement to the discovery of mines," for the young colony needed iron, and iron minerals had been discovered in eastern Massachusetts. This public offer and technical information on local iron deposits led the younger John Winthrop (q.v.) in the summer of 1641 to enlist the aid of investors in England and the colony to form the Company of Undertakers for the Iron Works in New England. By a vote of the Boston Town Meeting in February 1644, he received a grant of 3,000 acres of the common land at Braintree. It is probable that Winthrop erected a blast furnace at Braintree between 1644 and 1647, and that construction of a finery and chafery was begun during 1644 or 1645. The blast furnace was not successful, but the finery and chafery ultimately processed iron produced at Saugus. In March 1644, the colony

granted the company a 21-year monopoly to manufacture iron (provided it would meet the inhabitants' needs for iron within 2 years), with free use of wastelands, the privilege of erecting furnaces and forges in six places, exemption from general taxation, and the right to export iron when local demand had been satisfied. The General Court set a maximum sales price of £20 per ton of bar iron.

During 1646 and 1647, Winthrop's company built the first successful ironworks in America in the village of Hammersmith on the banks of the Saugus River near Lynn, Mass. The works, known historically by the names "Hammersmith" and "Saugus," comprised a blast furnace, two fineries, a chafery, and a rolling and slitting mill. The blast furnace produced pig iron from a mixture of local bog ore and ore from Nahant with charcoal—a mixture sufficiently self-fluxing so that additional flux, such as limestone or oyster shells, was not required. The pig iron output during August 1648 was at the rate of 7 tons a week. The works also produced bar iron and such finished products as cannon balls, hammer heads, pliers, pots, saws, scale weights, scythes, shovels, and skillets. In its day the Saugus works was a large-scale industrial plant and a prototype of United States heavy industry in general. Individuals evaluated the chances of success in a new venture, organized a company, risked their capital, bargained with the colonial government for the best terms on which to undertake the venture, hired specialists to build and operate the works, and participated in its management. The Saugus plant is considered the birthplace of the United States iron and steel industry. Of greater importance, it is the plant at which American colonists broke with many European traditions concerning the relationships of industry to government, management to labor, and state to church. The significance of this plant in the economic, social, and religious development of the United States is commemorated in its reconstruction, completed in 1954 by the First Iron Works Association of Saugus, Mass.

The Saugus works employed freemen, indentured servants, and, occasionally, Indians. Except for the indentured servants and a few skilled freemen, most of the workers were part-time employees who also worked on their farms or at trades. Highly skilled workers, such as the foreman of the blast furnace and the workman in charge of the water-powered blowing engine, were specialists, but the rest generally were not. Felling timber, sawing wood, making charcoal, weaving baskets for ore or charcoal, digging ore, and weighing iron provided variety in work and wages. Typical weekly wages in 1650 were \$6.60 for making charcoal and \$8.65 for charging the blast furnace with raw materials. The work week was six days from sunrise to sunset. A day's wage for weighing iron was 85 cents; for cutting the iron into marketable shapes, \$1.40. The company's charter exempted the workmen from all public charges, taxes, military service, and "watching for Indians." For about 50 full-time workers and an unknown number of part-time workers annual cash payrolls are estimated to have been \$8,000; to this should be added \$12,000 for housing, feeding, and clothing 35 indentured servants who received no cash wages.

The many deposits of iron ore scattered along the Atlantic seaboard, together with an abundance of wood and water power, soon provided an iron-

works in or near practically every large community. During the third quarter of the 17th century the industry was concentrated in Massachusetts and Connecticut. During the last quarter ironworks were established in northern New Jersey to smelt magnetic iron ores, which were richer than the New England bog and pond deposits.

The pig iron made in colonial blast furnaces was raw material for casting into molds for such articles as firebacks, kettles, pots, salt pans, skillets, and stove parts. It was also raw material for the manufacture of one kind of colonial bar iron, in which the cast iron was refined on a hearth to remove excess carbon. The pig iron was usually cast into sand molds directly from the blast furnace. A cast iron pot of about one-quart capacity, cast directly from the Saugus blast furnace, was the first product of colonial iron manufacture. The other type of colonial bar iron was obtained by heating iron ore with charcoal on a bloomery hearth without melting the extracted iron. This was a crude form of wrought iron. When carefully made, it had a carbon content sufficiently low so that the iron was malleable and ductile. It was forged or hammered into bars, which in turn were reheated and hammered into ax heads and other tools, bolts, hinges, pothooks, shutter hooks, agricultural implements, wagon tires, horseshoes, and household articles.

18th Century.—In the first half of the 18th century ironworks were built in New York, New Jersey, Pennsylvania, Delaware, Maryland, and Virginia. While Massachusetts and New Jersey were the leading iron producers during the last quarter of the 17th and the first quarter of the 18th centuries, Pennsylvania rapidly challenged their lead. In Pennsylvania, as in other colonies, lack of cheap transportation necessitated the location of ironworks near ore deposits, forests of oak, hickory, ash, chestnut, or pine, water power, labor, food supplies, and, in many instances, the market for cast and bar iron.

In the 18th century iron plantations flourished in Pennsylvania. An iron plantation was essentially a self-contained community, analogous to an Irish feudal barony. Its proprietor, like a Virginia tobacco planter, was in effect the governor of a community that depended on him for its welfare as well as its livelihood. Some of the iron plantations embraced as much as 10,000 acres. One of them was restored by the National Park Service at Hopewell Village, 6 miles southeast of Birdsboro, Berks County, Pa. Known as the Hopewell Village National Historic Site, it was established in 1938.

Beginning with a bloomery forge built by William Bird in 1743, the Hopewell plantation expanded until its population reached about 1,000. Included in it were an iron mine about 2 miles from the center of the village, forests in which wood was cut and made into charcoal, charcoal storage houses, and an ore roaster. There were also a dam with two headraces and a tailrace, a mill wheel, a blast furnace, a bridge over the west headrace to the blast furnace, slag piles, a casting house, a blacksmith shop, a wheelwright shop, tenant houses, barns, farms, a springhouse, a bakehouse, corncribs, a combination office and store, a carriage house, a schoolhouse, and the proprietor's mansion. The schoolhouse was probably also used as a church. The plantation produced iron for industrial use and iron cast into stoves and hollow ware. Most of the products

were shipped by boat or horseback to Philadelphia, the remainder being consumed on the plantation.

The geographical trend of the colonial iron industry to the west and south, as shown on Map 2, brought the first ironworks to Kentucky, Tennessee, and Georgia during the last quarter of the 18th century. While ironworks were in operation in both North Carolina and South Carolina prior to the American Revolution, the date of erection of the first ironworks in North Carolina is not clearly established. The westward and southward trend of the iron industry continued throughout the 19th century, when ironworks were established in Alabama, Arkansas, California, Colorado, Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Ohio, Oregon, Texas, Utah, Washington, Wisconsin, and Wyoming.

Measurements of the ruins of colonial blast furnaces suggest that the typical furnace was a

Periodically the slag and iron were drawn off through separate tapholes or notches, the slag hole being at a higher level than the iron hole. The charcoal was burned by a blast of cold air which entered the furnace just above the hearth. A large pair of bellows, usually made of leather, was operated by a water-driven wheel to supply the air or blast. Overshot water wheels in diameters up to 30 feet were used. In some instances a considerable area of land had to be flooded in back of an ironworks dam in order to provide the volume of water and drop in height required for water wheels. At the Saugus works, for example, about 1,000 acres were submerged. In northern colonies, where freezing weather prevailed during the winter, ironworks were usually idle when the water wheel froze.

Terms such as "bloomery," "forge," "finery," "refinery," "chafery," "ancony," "sowe iron," "pig iron," "bar iron," and "merchant bar" were in common use in the colonial iron industry, and some of them have persisted. Bloomery, also spelled bloomary, has several distinct meanings. One type of furnace in which an iron bloom was made directly from iron ore was known as a bloomery or forge and also as a block oven or block furnace. The term "bloomery" also referred to an ironworks consisting of a forge, a hammer for working the bloom, and a blowing engine to supply air to the forge. Similarly, the term "forge" was used interchangeably with "bloomery" to include the equipment. Many ironworks had a heating furnace to reheat blooms as well as other iron products before pressing or squeezing them under the hammer; the terms "bloomery" and "forge" also included this furnace.

A refinery was a furnace with a hearth similar to that in a bloomery furnace, in which pig iron from the blast furnace was placed in a charcoal fire to refine it into a malleable condition. In some processes iron ore was added to the hearth to assist in the refining. The main objective was to remove excess carbon, which made the pig iron too brittle for working either hot or cold. The refinery was also called a charcoal finery or charcoal refinery. The product of a refinery was a chunk of plastic and nearly white-hot iron called a half bloom, which was placed on an iron anvil and pounded with an iron hammer to squeeze out the molten slag. The hammered half bloom was reheated to a bright red color and rehammered to remove more slag. This operation yielded an ancony, which was a thick bar, rectangular in cross section, with a rough knob at each end. The term "ancony" applied broadly to a bloom which had been worked under a hammer to the required width and thickness except at the ends, which were not hammered. The ancony was an article of commerce. If it was further processed, it was placed in a chafery, a reheating hearth, and then hammered into bar iron, in dimensions up to 14 feet long, 2 inches wide, and $\frac{1}{2}$ inch thick. When cut into convenient lengths, these bars were sold as merchant bars.

Although such bars were bought by blacksmiths, locksmiths, and even householders, they were most frequently sold to peddlers and merchants. The term "merchant bar" was originally applied to a piece of iron sold from a peddler's wagon or over a merchant's counter. An English pamphlet of the early 18th century defined this term as "such shaped iron as is usually imported by the merchant, about an inch and a half or two inches broad and one-third thick, and squares of

Map. 2. Geographical trend of iron industry, 1646-1857.

four-sided, hollow stone stack about 20 feet high, from 20 to 24 feet square at the base, and tapering to 16 to 20 feet square at the top. The interior egg-shaped cavity was lined with slate or other heat-resisting stone. The furnace was built against the side of a hill so that workmen could more easily charge it through the open top. They dumped in alternate layers of bog ore or magnetic ore, charcoal, and flux (oyster shells or limestone). The lime in the shells or stone formed a slag with the unwanted materials in the ore. Hot gases from the burning charcoal reduced the iron from the ore, and heat from the charcoal melted the metallic iron and fused the slag. As the charge of iron ore, charcoal, and flux descended in the furnace, droplets of iron and slag collected in two layers in the hearth or bottom of the furnace, the lighter slag floating on the heavier iron.

different sizes." The term later included bars of steel. In the 19th century rolling mills were developed to roll iron into merchant bar sizes. When larger mills were built to roll steel sections heavier than merchant bar sizes, the older mills that continued to roll the smaller sizes of bars were called merchant mills. Some sections of steel rolled for general resale purposes are still known as merchant bars.

While the molten iron from many colonial blast furnaces was cast or run directly into molds having the form of hollow ware, a large amount was also run into a main trough which led to smaller troughs. The solidified iron in the main trough was called sowe iron or sow iron, and that in the smaller troughs pig iron, from the analogy of a sow with suckling pigs. Both sowe iron and pig iron were commercial products of the colonial blast furnace. The term "pig iron" has been retained to designate a class of iron made in the modern blast furnace.

During the 131 years of the colonial iron industry, extending from 1644 to 1775, the principal consumers of iron and iron products were the householders, merchants, peddlers, ship chandlers, and metal craftsmen, such as gunsmiths, locksmiths, and blacksmiths, living in the vicinity of ironworks. Lack of cheap transportation localized the iron industry, and there were no important colonial industrial consumers of iron, although, when British laws and import taxes were favorable, considerable amounts of iron were exported to England. The first shipment of colonial bar iron to England was made in 1718 by the Principio Company from its Principio Furnace in Maryland (see Map 1). An import tax of £2 ls. 6d. per ton was levied on the 3.5 tons in the shipment. The Principio Company was one of the leading exporters of colonial iron. In 1750, for example, it shipped to England 2,050 tons of iron, an amount which represented two thirds of all colonial exports and one fifth of colonial iron production for that year.

The rapid growth of the colonial iron industry between 1715 and 1775 was not realized by the British Parliament, partly because reports from colonial governors were inadequate or incomplete, and partly because the colonists did not publicize the nature and extent of their industry. Furthermore, Great Britain itself was divided on the desirability of expanding the colonial iron industry. British ironmasters, fearing competition, argued for a high tariff on pig iron and bar iron imported from the colonies, while manufacturers of iron wares, seeking cheap raw material, argued for colonial bar iron.

When Sweden fought Denmark, Hannover, Prussia, Russia, and Saxony in 1717, shipments of Swedish iron to Great Britain were suspended. In the following year, when shipments were resumed, British manufacturers sought another source of iron and looked to North America. Their petitions to Parliament to increase the number of colonial ironworks started a long controversy that resulted in no parliamentary action until 1750. Meanwhile, the depression of British industries in 1735 closed many factories. The contemporaneous arrival of bar iron from Maryland, Pennsylvania, and Virginia aggravated the controversy when it was found by British navy yards' tests that colonial iron was equal to the best grade of Swedish iron—the world's finest at that time. To complicate the controversy, the colonists were accused of depriving British in-

dustries of an important market in North America because they manufactured iron articles from their own iron. Finally, after three decades of intermittent deliberation, Parliament enacted a law which provided that after June 24, 1750, "no mill or other engine for slitting or rolling iron, or any plating forge to work with a trip hammer, or any furnace for making steel" should be built in the American colonies. Works of these types already built were permitted to continue in operation. Enforcement of the law was the responsibility of colonial governors, who ordered the sheriffs to take a census in their respective counties in order to ascertain the status of the colonial industry. The census did not reveal the true status: the colonists did not cooperate, and the sheriffs were not sufficiently skilled in iron manufacture to identify what they saw in all cases. Census reports sent to the British Board of Trade indicated the following:

Connecticut—8 plating mills and 1 steel furnace
 Maryland—1 plating mill
 Massachusetts—2 slitting mills and 2 plating mills
 New Jersey—1 slitting mill, 1 plating mill, and 1 steel furnace
 New York—1 plating mill
 Pennsylvania—1 slitting mill, 1 plating mill, and 2 steel furnaces

It is estimated that by 1775 the American iron industry had outstripped its British counterpart, since the colonists had an estimated 80 blast furnaces with an average capacity equal to or slightly larger than that of the 60 English blast furnaces, and an estimated 175 forges, as compared with a total of 135 in England and Wales. While the estimated annual world output of iron rose from 150,000 tons¹ in 1750 to 210,000 tons in 1775, the estimated annual output of colonial iron rose from 10,000 to 30,000 tons. British regulations permitted the shipment of iron from the American colonies only to Great Britain or its colonies until 1765, when shipments to Ireland were also allowed. Nearly all of the American iron exported went to England; small amounts of pig iron and bar iron were sent to Scotland. Exports from the American colonies averaged 2,800 tons of pig iron and 570 tons of bar iron from 1730 to 1775. During this period the highest and lowest exports of pig iron were, respectively, 5,303 tons in 1771 and 1,725 tons in 1730; bar iron exports were at a maximum of 2,222 tons in 1771 and a minimum of 4 tons in 1748. Virginia and Maryland were important exporters of pig iron, and Pennsylvania of bar iron; New England, New York, and the Carolinas also exported iron prior to the revolution.

British parliamentary attempts to restrict the growth of the colonial iron industry were a minor but significant contributory cause of the War of Independence, since they united the majority of colonial ironworks owners and managers in support of the revolutionary movement. The following signers of the Declaration of Independence were associated with the iron industry: Charles Carroll of Carrollton, who, as a lawyer, was in close contact with Maryland's iron industry; Stephen Hopkins, who was part owner of the Hope Furnace, on the Pawtuxet River, Rhode Island, which made cannon and cannon balls during the revolution; Philip Livingston, who was the son of the owner of a bloomery on Ancram Creek, Columbia County, New York; George Ross, who was a partner of Mark Bird in building

¹ Presumably long tons of 2,240 pounds each.

the Mary Ann Furnace in West Manheim Township, York County, Pa., which cast shot and shell for the Continental Army; James Smith, who owned the Hellam Forge, later known as the Codorus Forge and Furnace, in York County, Pennsylvania; and George Taylor, who worked in his youth as a filler at Durham Furnace in Bucks County, Pennsylvania, and later became sole lessee of this property (Durham Furnace was another outstanding supplier of iron for the Continental Army). A score or more ironmasters and ironworkers, including Brig. Gen. Daniel Morgan, Maj. Gen. Nathanael Greene, and Col. Ethan Allen, served as officers under George Washington, whose father, Augustine Washington, was one of the owners of the Principio Company.

Colonial Steel Industry.—Very little steel was made in colonial America, and until the Bessemer process was used in the 1860's only a small amount of steel in comparison with iron was made in the United States. The colonists relied mainly on England for steel.

It is believed that Samuel Higley made the first colonial steel at Simsbury, Conn., between 1725 and 1728, and that he used the cementation process. The product of the cementation process was not uniform in chemical composition or in internal structure. Carbon was absorbed largely on the surface of the bar and only to a slight depth. The carbon content of the inner portion or core of the bar was much less than the maximum content of about 2 per cent carbon at the surface. The frequent presence of bands or threads of slag within the product also did not permit the steel to develop uniform properties. Blisters that formed on the surface gave this product the name of blister steel. In addition, it was expensive to make, since it required considerable equipment and time for a relatively small output. Yet it served the demand for a material stronger and harder than iron which could be made into edge tools and firearms.

The second steelworks appears to have been built in 1734 at Trenton, N. J., for the manufacture of edge tools. At least six other steelworks had been built in Massachusetts, Connecticut, New Jersey, and Pennsylvania by 1750, the date beyond which the British Parliament prohibited the erection of new steelworks, slitting mills, and plating mills in the American colonies. By 1776 steelworks had also been established in Rhode Island and New York.

United States Iron and Steel Industry, 1783-1864.—The significant developments in the iron and steel industry of the United States from 1783, when a rolling mill was built in Delaware, to 1864, when Bessemer steel was first made on a commercial scale, are listed in the following chronology:

- 1783—Rolling mill built near Wilmington, Del. It rolled Swedish and Russian iron to be made into cut nails by a New York factory.
- 1787—Era Furnace built in York County, S.C.
- 1788—Etna Furnace built in York County, S.C.
- 1790—Blue lump iron ore discovered in Fayette County, Pennsylvania, by John Hayden of Haydentown.
- 1790—Tennessee's first ironworks, a bloomery, built at Embreeville, Washington County.
- 1791—Kentucky's first blast furnace, known as the Bourbon Furnace or Slate Furnace, built by Jacob Meyer on Slate Creek, Bath County.
- 1794—Foundry cupola, a furnace for remelting pig iron to be cast into product form, patented by John Wilkinson.

- 1800—Iron mines opened in Lake Champlain district of New York. They provided ore for forges and furnaces subsequently erected in the district.
- 1801—Ironworks built at Willsboro Falls, Essex County, N.Y. by George Throop, Levi. Highly, and Charles Kane to make anchors, using Champlain ore.
- 1805—First successful foundry built in Pittsburgh, Pa., by Joseph McClurg, Joseph Smith, and John Gormley. Later known as McClurg's and McKnight's, it cast cannon, howitzers, balls, and shells used in the War of 1812 by Comdr. Oliver Hazard Perry on Lake Erie and by Gen. Andrew Jackson at New Orleans.
- 1806—Rolling mill built in Southfield, Delaware County, Pa.
- 1811—Pittsburgh Rolling Mill built in Pittsburgh, Pa.
- 1816—Wire fences made at White and Hazard Works, Chester County, Pennsylvania.
- 1816—Plumstock Works, first rolling mill to roll flat iron bars in the United States, erected in Fayette County, Pennsylvania, by Isaac Meason.
- 1818—Crucible steel plant built at Valley Forge, Pa., by James Wood, John Parkins, and John Parkins, Jr. See also entry for 1832.
- 1819—Bituminous coal first used in blast furnace experiment to make pig iron at Bear Furnace, Armstrong County, Pennsylvania.
- 1819—Coke first used in blast furnace experiment to make pig iron at Bear Furnace, Armstrong County, Pennsylvania. The furnace was built to use coke and cold blasts; steam-driven blast was too weak for successful operation. See also entries for 1834 and 1835.
- 1819—Angle iron allegedly first rolled in the United States by Samuel Leonard at the Union Rolling Mill, Pittsburgh, Pa.
- 1820—Boiler plates first rolled by Dr. Charles Lloyd Lukens at the Brandywine Rolling Mill, Coatesville, Pa.
- 1826—Malleable iron made by Seth Boyden at Newark, N.J.
- 1826—Wire netting made by Charles Barnard at Norwich, Conn.
- 1827—Anthracite coal, mixed with charcoal or coke, used in blast furnace experiment in Perry County, Pennsylvania, by Peter Rittner.
- 1827—Ohio's first blast furnace, Franklin Furnace, built in Green Township, Scioto County, by Daniel Young, John Young, Jesse Y. Whitcomb, Josiah Merrill, John Hurd, and Martin Ruter, all of New Hampshire.
- 1828—Scioto Furnace, a blast furnace, built on Frederick Creek, 11 miles east-northeast of Portsmouth, Ohio, by Gen. William Kendall.
- 1830—Terneplate (iron coated with an alloy of lead and tin) allegedly made at Philadelphia, Pa. (Actually, the large-scale manufacture of terneplate in the United States began only after the McKinley Act, q.v., became effective in July 1891.)
- 1830—T-rail invented by Robert Livingston Stevens, president of the Camden and Amboy Railroad, who also designed the hook-headed spike and other railroad track accessories. The first T-rails weighed 36 pounds per yard.
- 1830—Furnace for welding pipe, the first in the United States, built in Philadelphia, Pa., by Morris, Tasker & Morris.
- 1832—Crucible steel first made on a commercial scale in the United States at the Cincinnati (Ohio) Steel Works, owned by Dr. William Garrard and his brother. The steel, which was made from blister bar, was used to manufacture saws, axes, files, and the blades of the first McCormick reaper.
- 1832—Pinmaking machine invented by John Ireland Howe of Derby, Conn.
- 1833—Anthracite coal in combination with "strong blast, preferably heated," patented by Dr. Frederick W. Geissenhainer, a New York clergyman.
- 1834—Hot blast given first "practical application" in a United States blast furnace at Oxford Furnace, New Jersey, by William Henry.
- 1835—Coke first used successfully as a blast furnace fuel in Mary Ann Furnace, Huntingdon County, Pennsylvania, by William Firmstone.

- 1835—Horseshoe-manufacturing machine patented by Henry Burden of Troy, N.Y.
- 1839—Anthracite coal used successfully in a blast furnace by Benjamin Perry at Pioneer Furnace, Pottsville, Pa., and by David Thomas at Lehigh Crane Iron Company, Catasauqua, Pa.
- 1840—Rotary squeezer to remove slag from "puddled iron" (wrought iron) invented and patented by Henry Burden of Troy, N.Y.
- 1841—Wire rope first made in the United States by John A. Roebling at Saxonburg, Butler County, Pa.
- 1842—Recovery of unburnt blast furnace gas for burning under steam boilers first accomplished at Greenwood Furnace, Orange County, New York, in accordance with the method developed by Friedrich von Faber du Faur of Wasseraalengen, Germany.
- 1842—Connellsville coke, made in western Pennsylvania, delivered by barge to foundries in Cincinnati, Ohio.
- 1844—Lake Superior iron deposits first discovered by white men. The discovery was made on September 19 by William Austin Burt near the eastern end of Teal Lake in northern Michigan.
- 1844—Iron T-rails, weighing 50 pounds per yard, made at Mount Savage Rolling Mill, Allegany County, Maryland.
- 1845—First wrought iron T-rail rolled in the United States at the Montour Iron Works, Danville, Pa.
- 1845—Bituminous coal successfully used in a blast furnace in Mercer County, Pennsylvania, and at Lowellville, Mahoning County, Ohio.
- 1845—Howe-type truss railroad bridge built by Richard B. Osborne at Manayunk (now part of Philadelphia), Pa., with cast iron top chord and web braces and wrought iron bottom chord and vertical web members.
- 1846—Observation that iron in a finery fire was heated by the blast of air without the aid of charcoal made by William Kelly at the Suwanee Iron Works & Union Forge, Eddyville, Ky.
- 1847—Empire Furnace, a blast furnace, built in Vernon Township, Trumbull County, Ohio, by Jefferson W. and Obadiah Glidden.
- 1848—Arrival of Andrew Carnegie, his brother Thomas, and his parents in the United States from Dunfermline, Scotland.
- 1852—Blowing engines that increased output of pig iron from blast furnaces built by David Thomas of Catasauqua, Pa.
- 1852—Lake Superior ore first used in a blast furnace at Sharpsville, Mercer County, Pa.
- 1854—First wrought iron beams to be rolled in the United States for building construction produced by Peter Cooper, at Trenton, N.J.
- 1855—Sault Ste. Marie Canal, connecting Lake Superior and Lake Huron, built by Charles T. Harvey.
- 1855—30-foot rails rolled at Cambria Iron Works, Johnstown, Pa.
- 1857—Converter (Bessemer) process of steelmaking patented by William Kelly of Eddyville, Ky.
- 1857—Approximate date when press was first used to straighten rails.
- 1857—Continuous process of hardening and tempering music wire developed and patented by Ichabod Washburn of Worcester, Mass.
- 1857—Chicago Rolling Mill built by Capt. Eber B. Ward of Detroit in Chicago, Ill., to reroll iron rails.
- 1857—First Michigan iron ore railway completed from deposits on Marquette Iron Range to the port of Marquette on Lake Superior.
- 1857—Three-high rolling mill invented by John Fritz, chief engineer and general superintendent of the Cambria Iron Works, Johnstown, Pa.
- 1858—
- 1859—Tin plate (iron coated with tin) made by C. G. Hussey & Company, Pittsburgh, Pa. (Actually, the large-scale manufacture of tin plate in the United States began only after the McKinley Act, q.v., became effective in July 1891.)
- 1859—Zinc made in experimental furnace by Joseph Wharton, manager of the Lehigh Zinc Company, South Bethlehem (now part of Bethlehem), Pa. This marked the beginning of metallic zinc manufacture in the United States.
- 1859—
- 1860—Cold rolling of iron and steel invented and patented by Bernard Lauth, a partner of Benjamin Franklin Jones, founder of Jones & Laughlin Steel Corporation, Pittsburgh, Pa.
- 1861—Approximate date when continuous annealing, cleaning, and galvanizing of wire (an English invention) was installed by Ichabod Washburn at the Washburn and Moen Works, Worcester, Mass.
- 1862—Wrought iron and steel columns, used for bridges and other structures, invented by Samuel J. Reeves of the Phoenix Iron Company, Phoenixville, Pa.
- 1864—Bessemer steel first made in the United States on a commercial scale by William Franklin Durfee, acting for the Kelly Pneumatic Process Company, Wyandotte, Mich.

Iron.—The westward and southward expansion of the iron industry, which began in the latter part of the colonial era, continued after 1783. By 1800, as shown on Map 2, ironworks were located in all of the original 13 states and also in Maine, Vermont, Tennessee, and Kentucky and in that part of Virginia which became West Virginia.

The arrival of the Industrial Revolution in the United States created new demands for iron in the manufacture of tools and machinery. The rapid rise of manufacturing in the northeastern part of the country in the early 19th century was a major factor in the basic shift in the national economy from agriculture to industry. Manufacturing in this area stimulated the expansion in capacity of existing ironworks and the erection of new works, particularly in Pennsylvania. Nevertheless, lack of cheap transportation continued to localize the manufacture of iron largely in areas near markets until the latter half of the 19th century. Even as late as 1857, when several thousand miles of railroads were in operation, iron products were readily available only to the 500 communities in which ironworks were located. The majority of these communities were in Pennsylvania, Virginia, Ohio, Tennessee, New York, and Kentucky, in which 690 blast furnaces had been built; the remaining furnaces were in Maine, New Hampshire, Vermont, Massachusetts, Connecticut, New Jersey, Delaware, Maryland, North Carolina, South Carolina, Georgia, Alabama, Indiana, Illinois, Michigan, Wisconsin, and Missouri.

The United States iron industry during the first half of the 19th century was characterized to a greater degree by expanded output than by improvements in technology, although many important technical advances were made, as indicated in the preceding chronology. At the beginning of this period charcoal was the only fuel successfully used in United States blast furnaces; at the end, charcoal, anthracite coal, bituminous coal, and coke were all employed.² Coke, hot blast, and blowing engines were important technical advances in increasing the efficiency of blast furnaces and consequently the output of pig iron. Rolling mills for bars, plates, and rails; the process of cold rolling iron; the continuous annealing, cleaning, and galvanizing of wire; and the making of wire rope were equally important developments in the manufacture of iron products.

The enormous increase in the annual output of pig iron was the outstanding achievement of this period of the iron industry. The estimated production of pig iron and bar iron totaled 30,000 tons³ in 1775 and 50,000 tons in 1800. In 1864 the production of pig iron alone totaled 1,135,996

² All of the 260 modern blast furnaces in the United States on Jan. 1, 1954, burned coke.

³ Presumably long tons of 2,240 pounds each.

net tons, of which 684,018 tons were made with anthracite coal, 241,853 tons with charcoal, and 210,125 tons with either bituminous coal or coke.

Two achievements in this period that made possible the industrial expansion of the latter half of the 19th century and its continuance through the first half of the 20th century were the discovery of the Lake Superior iron ore deposits and the building of the Soo (Sault Ste. Marie) Canal. A government surveyor, William Austin Burt, discovered the first of the Lake Superior deposits in northern Michigan in 1844, and a young scales salesman, Charles T. Harvey, envisioning Lake Superior ore in Eastern furnaces, organized and managed the company which completed the 5,700-foot Soo Canal in 1855 to connect Lake Superior and Lake Huron. Without the rich ores of the Lake Superior district and without cheap transportation to utilize them, it is doubtful if the United States would have attained its position as the leading industrial nation. A century after their discovery, the Lake Superior deposits were still among the richest and most extensive in the world, and through the two Soo canals more tonnage was transported annually than through any other canal.

Steel.—The manufacture of cemented steel, which was practiced during the colonial era, continued on a small scale during the first half of the 19th century. The output of cemented steel in 1810 was 917 long tons, as compared with 53,908 long tons of cast iron. By 1830 the annual capacity of the 14 steel furnaces in the United States totaled 1,600 tons. The introduction of the crucible process from England in 1832 did not lead to any considerable increase in steel production. The Compromise Tariff of 1833 closed the first crucible steel plant in Cincinnati, and the tariffs of 1846 and 1857 gave no encouragement to this steelmaking method. The full development of the crucible process occurred in the latter half of the 19th century.

Neither the cementation process nor the crucible process could make steel cheaply or in large amounts. The small quantities which were produced were used mainly in tools, instruments, small arms, and machine parts. While many articles were made of cast iron, its use in structures and machinery was limited because it was brittle and weak in tension. (The cast irons in modern use had not been developed.) Consequently, the further industrial development of the United States awaited a steelmaking method that could satisfy the mounting demand for a cheap structural material stronger than cast iron and bar iron.

The nearly simultaneous invention of the Bessemer process by Sir Henry Bessemer in England between 1854 and 1856 and of the Kelly pneumatic process by William Kelly in Kentucky between 1846 and 1857 provided such a steelmaking technique, now known as the Bessemer process. Each of the two inventors blew air through molten pig iron to burn the excess carbon and other elements, the burning supplying the heat required to keep the metal molten. Each had to rely on others for technical improvements to make the process commercially workable. Each was an outstanding pioneer to whom the industry and mankind are indebted.

The Bessemer process provided the cheap, strong steel that made possible the great expansion in the building of railroads and bridges, new types of textile, printing, and other machinery, steel ships, telegraph lines, agricultural imple-

ments, pipelines, frameworks of buildings, and the electrical industry. At the same time, the widening demand for steel for small articles, ranging from bicycle spokes to safety pins, was also met by Bessemer steel. The flood of steel that poured from United States converters in the latter half of the 19th century began with the making of the first commercial heat of Bessemer steel in the country by William Franklin Durfee at Wyandotte, Mich., in 1864. The Bessemer process persisted as an important steelmaking method, despite the development of the open-hearth process in the latter part of the 19th century and the electric furnace process in the first decade of the 20th century.

United States Iron and Steel Industry Since 1865.—While United States iron and steel manufacture made notable technical advances after 1865, these were overshadowed by the consolidation of iron and steel plants into combinations of companies during the last quarter of the 19th and the first decade of the 20th centuries. Economies of operation resulting from consolidations generally resulted in lower prices of iron and steel. The extensive development of transportation by boat and rail favored the consolidation of many of the existing companies into organizations that owned ore, coal, and limestone deposits, railroads, and steamship companies, as well as completely integrated production units that controlled the quality of the product from the mine to the consumer.

Technological Progress.—The United States iron and steel industry grew rapidly after 1865 because it helped the growth of so many other industries, among them the railroad, petroleum, electrical, farm equipment, automobile, and machine tool industries. The development of each of them required more useful iron and steel products, new types of iron and steel, and lower iron and steel costs.

New methods of working steel kept pace with new steelmaking methods. Technological development followed two paths, one mechanical and the other metallurgical. Methods of hot rolling steel into a variety of semifinished products, which in turn were rolled into rails, structural shapes, and pipe, were put on an automatic basis. Knowledge acquired about the internal structure of steel permitted the development of continuous rolling mills to reduce steel to paper thickness. Hand methods of drawing wire were replaced by automatic processes that drew the many sizes and kinds of wire required by such diverse products as cables for suspension bridges and springs for typewriters. Methods of coating steel with cadmium, copper, lead, tin, and zinc were improved and mechanized, and the quality of the coatings was made more uniform. The development of methods of welding steel led to significant changes in the design of many products in which steel assemblies were used.

The development of the open hearth and electric furnace for steelmaking required improved metallurgical and mechanical techniques. These in turn required better furnace refractories, more efficient methods of burning fuels, and sensitive, automatic devices for measuring temperature and controlling chemical reactions in steelmaking and iron manufacture. The microscope opened the way to a better appreciation of the complex nature of commercial irons and steels, and resulted in the rapid development of methods of heat treating iron and steel to enhance their properties. This line of investigation also led to the creation of a

Map 3.

series of alloy steels and alloy irons containing elements added in order to obtain properties not present in conventional plain carbon steels or cast irons, such as an extreme resistance to corrosion, elevated temperature, and repeated stressing.

One outstanding development problem concerned the beneficiation or enrichment of the lower grades of iron ore in the United States. The Lake Superior iron ore district, embracing the iron ranges in Minnesota, Wisconsin, and Michigan, produced 85 per cent of the ore consumed by the United States. The life of the high-grade deposits in these ranges was estimated in 1945 to be 20 years; and the known reserves containing over 50 per cent metallic iron were estimated at 500,000,000 long tons. From 1941 through 1945 the United States produced 482,055,313 long tons of iron ore, of which 409,834,624 long tons came from the Lake Superior district. Tremendous deposits in the district containing 30 to 50 per cent iron were also worked. Ores from some of these deposits were blended with the high-grade ores, and others were beneficiated or concentrated by mechanical methods. But the cost of such beneficiation increased with the leanness of the ore. In 1945 there were also estimated to be 60 billion long tons of taconite in the Lake Superior district. Taconite is a general term applied to several iron mineral formations containing 20 to 35 per cent iron. The Minnesota deposits are estimated to contain 27 billion tons, much of which has an iron content of 30 to 35 per cent. These deposits are too lean for direct smelting in United States blast furnaces.

Beginning in 1942 research was intensified to develop processes to beneficiate or concentrate the iron minerals in the low-grade deposits. In 1948 research on some of the taconite deposits of Minnesota materialized in the operation of a pilot plant at Aurora, Minn., to produce 200,000 tons of concentrates annually. By 1954 this operation had yielded sufficient information to warrant beginning construction of a 10,500,000-ton plant near Aurora. Similarly, a plant with a capacity of 300,000 tons at Babbitt, Minn., was the basis of a plant completed in 1955 at Silver Bay, Minn. Other new plants for concentrating low-grade iron deposits, in operation or scheduled for construction, were located at Mountain Iron and Virginia, Minn., and Ishpeming and Humboldt, Mich. When all of these plants were operating at full capacity, the output of iron mineral concentrates was expected to total about 21,400,000 tons annually.

Production.—The location of the principal iron and steel producing centers and sources of raw materials in the United States as of 1954 are shown on Map 3. From 1941 through 1953 the national production of crude steel totaled about 1,152 million tons, or more than the output of the 26-year period of 1915 through 1940. This accelerated production so depleted the high-grade iron ore within the United States that worldwide exploration for new sources of ore was undertaken after World War II and was continued in the 1950's. In 1954 iron ore from every continent except Antarctica and Australia was smelted in United States blast furnaces to produce pig iron or charged into steelmaking furnaces, the imported ore totaling 15,782,530 net tons. The supplying countries, listed in the order of the amount of ore imported from each, were Venezuela, Canada, Peru, Chile, Sweden, Liberia, Brazil, British West Africa, Mexico, Dominican Republic, Cuba, Algeria, Iran, Great Britain, and Spain.

The magnitude of the demand for iron ore is evident from a few statistics on the production of iron and steel. Nearly 2 tons of iron ore containing a minimum of 50 per cent iron are required to produce 1 ton of pig iron, the small balance of the required iron being supplied by scrap. During the month of March 1953, 6,601,113 net tons of standard grades of pig iron were produced by blast furnaces in the United States. In the same month most of the pig iron, together with approximately equal amounts of scrap iron and steel and a small amount of iron ore, was charged into steelmaking furnaces to produce 10,168,000 net tons of crude steel. That monthly output of steel was equivalent to about 7,500,000 tons of finished steel products, or enough to provide steel for all of the following: 2 million automobiles; 1 million kitchen stoves; 1 million household refrigerators; 1 million washing machines; 10,000 railroad box cars; all the steel shipped directly from steel mills in 1952 for ordnance and other military purposes, aircraft, oil and gas drilling, mining, quarrying, and lumbering; cutlery and utensils for 8 million kitchens; and a small amount of steel for other purposes.

CANADA

Development of the Iron Industry.—The St. Maurice Forges, erected in 1737 three miles west of Three Rivers (Trois-Rivières), Quebec, were the first ironworks in Canada. They comprised a blast furnace and, by 1747, two "great forges" and two "lesser ones," which were built by Cugnet et Cie with the aid of a royal license and 10,000 livres from King Louis XV of France. The blast furnace was rebuilt in 1743 and modified between 1793 and 1809. By 1880 it was 30 feet high and had internal diameters of 2½ feet at the hearth, 7 feet at the bosh, and 3½ feet at the throat. Two tuyères supplied a blast of cold air to burn charcoal obtained from local trees, and local ore and limestone were smelted to produce 4 tons of pig iron daily. When the exhaustion of local ore and fuel finally shut down the blast furnace in 1883, it had earned the designation of the oldest active furnace in North America.

Another important ironworks was built about 1860 by Messrs. Larue & Co. at Radnor Forges, Champlain County, Quebec, a site which coincided with one chosen in 1672 by Louis de Buade, comte de Frontenac, as the most desirable location for a blast furnace in the St. Maurice district. The same company constructed a foundry at Three Rivers. The blast furnace originally produced 4 tons of pig iron daily; in 1892 a new blast furnace began operation at the rate of 24 tons daily. The foundry made cast iron wheels for railroad cars, and a pair of these wheels that had run 150,000 miles was displayed at the international exhibition held in London in 1862. Radnor Forges continued to make iron intermittently until 1911, when the exhaustion of suitable ores closed the ironworks.

The date of erection, location, type of works, and products of these and other early Canadian ironworks are listed in the following chronology:

- 1737—Three miles west of Three Rivers, St. Maurice County, Quebec; blast furnace and four forges, all known as St. Maurice Forges; pig iron, castings such as cannons, mortars, shot, pots, kettles, and stove parts, and bar iron.
- 1798—East bank of Batiscan River, Champlain County, Quebec; blast furnace and two forges; pig iron, castings, and bar iron.

- 1800—Lyndhurst (formerly Furnace Falls), on Gananoque River, Leeds County, Ontario; blast furnace and forges; pots, kettles, and bar iron.
- 1821—Normandale (formerly Potter's Creek), Norfolk County, Ontario; blast furnace; stove parts and kettles.
- 1825—Clementsport, Annapolis County, Nova Scotia; blast furnace; pig iron.
- 1830—Marmora, Hastings County, Ontario; blast furnace; pig iron.
- 1837—Marmora, Hastings County, Ontario; a second blast furnace erected to make pig iron for conversion into bar iron.
- 1848—Woodstock, Carleton County, New Brunswick; blast furnace; pig iron.
- 1850—Londonderry, Colchester County, Nova Scotia; forge; bar iron.
- 1854—Houghton, Norfolk County, Ontario; blast furnace; pig iron.
- 1856—Nictaux Falls, Annapolis County, Nova Scotia; two blast furnaces; pig iron.
- 1857—Montreal, Quebec; rolling mills; iron sheets, hoops, and nails.
- 1857—Hull, Hull County, Quebec; blast furnace; pig iron.
- 1860—Radnor Forges, Champlain County, Quebec; blast furnace, forge, and rolling mill; pig iron, wrought iron for the manufacture of railroad car axles, scythes, and nail rod iron.
- 1860—Three Rivers, St. Maurice County, Quebec; foundry; cast iron wheels for railroad cars.
- 1860—Bloomfield, Digby County, Nova Scotia; blast furnace; pig iron.
- 1860—Toronto, Ontario; rolling mills, rerolled iron rail products.

Many of the early ironworks depended on local ore and wood for charcoal, and they closed when these were depleted. Although some skilled labor was available, ready access to farm lands made the workers independent of industry, and operations were sometimes curtailed by labor shortages. Moreover, the lack of cheap transportation restricted the availability of ore and fuel and markets for the products of the ironworks, and competition with foreign products and business depressions hampered profitable operations. By 1896 only six blast furnaces produced pig iron in Canada: one in Hamilton, Ontario, with a daily capacity of 200 net tons; one in Ferrona, Nova Scotia, 125 net tons; one in Londonderry, Nova Scotia, 100 net tons; one in Radnor Forges, Quebec, 25 net tons; and two in Drummondville, Quebec, 7 and 8 net tons, respectively.

Thereafter the number of blast furnaces increased as the construction of steel plants provided a demand for pig iron to be refined into steel, and as Canada's expanding industrial needs required greater quantities of pig iron for remelting in foundries making cast iron products. The annual capacity of Canadian blast furnaces in 1952 is shown in Table 2.

Table 2—ANNUAL CAPACITY OF BLAST FURNACES IN CANADA, 1952

Company and location	Number of furnaces	Annual capacity (net tons)
Algoma Steel Corporation, Limited, Sault Ste. Marie, Ontario	5	1,058,000
Canadian Furnace Company, Limited, Port Colborne, Ontario	2	223,000
Dominion Foundries and Steel Limited, Hamilton, Ontario	1	320,000
Dominion Iron & Steel Limited, Sydney, Nova Scotia	3	595,000
Steel Company of Canada, Limited, Hamilton, Ontario	4	1,250,000
Total	15	3,446,000

The output of Canadian pig iron rose from about 96,000 tons in 1900 to about 920,000 tons in 1911. In 1954 production of pig iron totaled 2,317,839 tons.

Development of the Steel Industry.—By 1879 imported mild steel was replacing wrought iron in Canada for some products, particularly axles for railroad cars. The shortage of wrought iron and scrap iron as raw materials for the works of the Nova Scotia Forge Company, combined with the prospect of using pig iron and imported scrap steel as raw materials for the Siemens-Martin open-hearth process then being developed in France and Great Britain, led to the formation of a new company, the Nova Scotia Steel Company, in 1882. In the following year, at its works in Trenton, Nova Scotia, steel was successfully manufactured on a commercial scale for the first time in Canada. The old company forged steel ingots purchased from the new company, for which it also provided maintenance parts and service. This interdependence resulted in the combination of the two as the Nova Scotia Steel and Forge Company, which produced steel for agricultural implements, steel angles, flats, special sections, and squares, rivet steel, railway fish-plates, plow plates, nail plate, and rails. In 1892 the New Glasgow Coal, Iron and Railway Company erected a blast furnace at New Glasgow, Nova Scotia. About one half of its pig iron output was supplied to the Nova Scotia Steel and Forge Company, and in 1895 the two companies were combined under the name of the original steel producer, Nova Scotia Steel Company.

One of the four principal segments of the Canadian steel industry was founded at Sydney, Nova Scotia, in 1899, following the loss of the New England coal market by the Dominion Coal Company. Both geographical and economic factors favored Sydney as a site for a steel plant. Cape Breton coal and Newfoundland iron ore and limestone were readily accessible to Sydney's harbor during the eight ice-free months, and a grant of land on the harbor and exemption from local taxation for 20 years were offered to induce selection of the city. Moreover, Canada's demand for steel was growing, and Sydney products could also easily be shipped to European markets. Of more immediate concern was the finding of a market for the Dominion Coal Company's Cape Breton coal. A stockholder of that company, Henry M. Whitney of Boston, proposed the construction of a steel plant as a market for the coal. This proposal resulted in the formation of the Dominion Iron and Steel Company and the eventual erection of coke ovens, blast furnaces, open-hearth furnaces, a blooming mill, a rail and billet mill, a bar and rod mill, and wire and nail mills. In the 1950's the Sydney steel plant and additions to it were operated by the Dominion Steel & Coal Corporation, Limited. The Sydney plant used iron ore from the Wabana mines on Bell Island, Newfoundland, limestone from deposits at Port au Port, Newfoundland, and coal from the Sydney coal field, 13 miles distant from the plant, and from two other Nova Scotian fields, the Cumberland field near Springhill and the Pictou field near New Glasgow.

While the steel industry was developing in Nova Scotia, a similar development took place in Ontario. In 1883 the London Steelworks Company of London, Ontario, built a 30-ton Siemens open-hearth furnace and a rolling mill to produce steel castings, car wheels, steel round

bars and flat bars, and steel coil springs. A puddling furnace and steam hammers were added in the following year. In 1893 the city of Hamilton offered a free site and a bonus of \$40,000 to any company which would spend \$400,000 in building a smelting works with a daily capacity of 150 tons before Dec. 31, 1894, and an additional bonus of \$60,000 if the company would erect a steel plant by Dec. 31, 1896. The time limit was subsequently extended by the city. The offer was accepted by the Hamilton Blast Furnace Company, which completed a blast furnace at Hamilton in 1895 and a steel plant, puddling furnaces, and a spike factory in 1897. The use of Lake Superior ore, after other ores had been found to be unsuitable, was an important factor in the success of this company.

Both of these companies were components of the Hamilton Steel and Iron Company, Limited, which in turn was one of the five companies which merged in 1910 to form the Steel Company of Canada, Limited, the second of the major components of the Canadian steel industry. The other four companies in the merger were the Montreal Rolling Mills Company, the Canada Screw Company, Limited, the Dominion Wire Manufacturing Company, Limited, and the Canada Bolt and Nut Company, Limited. Each of the five companies which combined to form the Steel Company of Canada, Limited, had in turn resulted from the merging of a number of producers and manufacturers of iron and steel. Some of these subsidiary or predecessor companies, with their dates of incorporation and typical products, are listed as follows under the five companies:

<i>Hamilton Steel and Iron Company, Limited, Hamilton, Ontario (1910):</i>	Bar iron, iron fishplates, bolts, spikes, steel bars
<i>Ontario Rolling Mills Co., Swansea, Ontario (1861)</i>	Iron bars, nail plate, iron products from rerolled rails
<i>Hamilton Iron & Forging Co., Hamilton, Ontario (1880)</i>	
<i>Hamilton Blast Furnace Company, Hamilton, Ontario (1895)</i>	Pig iron for foundries
<i>Windemere Rolling Mills, Toronto, Ontario</i>	
<i>London Steelworks Company, London, Ontario (1895)</i>	Steel castings, bar steel, bar iron
<i>American Nail Works</i>	Iron nails
<i>Montreal Rolling Mills Company, Montreal, Quebec (1868):</i>	Cut nails, wire nails, tacks, pipe, tubing
<i>Hodgson Iron and Tube Co., Montreal, Quebec (1902)</i>	Butt-welded tubing
<i>J. & C. Hodgson, St. Henri, Quebec (1888)</i>	Butt-welded tubing
<i>Pillow-Hersey Mfg. Co., Ltd., Montreal, Quebec (1887)</i>	Iron bars for bolts and nuts, cut nails, spikes, horse-shoe nails
<i>Pillow & Hersey Co., Montreal, Quebec (1876)</i>	Plate for cut nails, bars, bolt and nut stock, nails, carriage bolts, felly plates for wheel manufacture
<i>John Bigelow, Montreal, Quebec (1849)</i>	Cut nails
<i>Canada Screw Company, Limited, Hamilton, Ontario (1866):</i>	Screws, tacks
<i>Ontario Tack Co., Hamilton, Ontario (1885)</i>	Tacks, wire, nails
<i>Western Wire & Nail Co. Peerless Wire Co.</i>	Fine wire, coppered wire
<i>Dominion Wire Manufacturing Company, Limited, Lachine, Quebec (1883):</i>	Wire, galvanized wire, wire rope, nails, screws
<i>Dominion Barb Wire Company, Limited, Montreal, Quebec</i>	Galvanized barbed wire, wire rope

<i>Canada Bolt and Nut Company, Limited, Toronto, Ontario (1919):</i>	Bolts, nuts
<i>Gananoque Bolt Co. (1905)</i>	Bolts, nuts
<i>Toronto Bolt & Forging Co. (1900), Gananoque and Swansea, Ontario</i>	
<i>MacDonell Rolling Mills Co., Sunnyside, Ontario</i>	
<i>Geo. Gillies Company, Limited (1893), Gananoque, Ontario</i>	
<i>Geo. Gillies, Reg'd (1874), Gananoque, Ontario</i>	Harrows, cultivators, bolts, nuts
<i>Top Lifting Co., St. Catharines, Ontario</i>	Bow sockets, top joints, buggy rails
<i>Byers & Matthews, Gananoque, Ontario</i>	Fifth wheels
<i>R. P. Colton</i>	
<i>Swansea Forging Co. (1895), Swansea, Ontario</i>	Farm implements
<i>Ontario Bolt & Forge Co. (1891), Swansea, Ontario</i>	
<i>Dundas Horseshoe & Drop Forging Co., Dundas, Ontario</i>	
<i>Ontario Bolt & Iron Co. (1885)</i>	
<i>Lillie Bolt & Nut Co., Perth, Ontario</i>	
<i>Dominion Bolt & Iron Co. (1893), Swansea, Ontario</i>	Bolts, nuts, spikes, rivets
<i>Dominion Bolt & Nut Co. (1880), Toronto, Ontario</i>	Bolts
<i>Dominion Bolt Works (1879), Toronto, Ontario</i>	Track bolts and spikes, nuts, tire and stove bolts, rivets, bridge rods
<i>Canadian Bolt Co. (1868), Perth and Toronto, Ontario</i>	Bolts, nuts
<i>Brantford Screw Company (1901), Brantford, Ontario</i>	Bolts, nuts, rivets, screws
<i>Chalcraft Screw Co. (1898)</i>	
<i>Belleville Iron & Horse-shoe Co. (1907), Belleville, Ontario</i>	Horseshoes, spikes
<i>Toronto & Belleville Rolling Mills Co. (1906), Belleville, Ontario</i>	
<i>T. M. Kirkwood Company, Belleville, Ontario</i>	
<i>Iron & Steel Co. of Canada, Belleville, Ontario</i>	
<i>Abbott-Mitchell Iron & Steel Co. (1898), Belleville, Ontario</i>	Spikes, nails
<i>Metropolitan Rolling Mills (1883), Montreal, Quebec</i>	

The search for a market for water power led to the establishment of another important Canadian iron and steel center, at Sault Ste. Marie, Ontario. In 1894 the town of Sault Ste. Marie sold its power canal and powerhouse to Francis Hector Clergue and E. V. Douglas. The Lake Superior Power Company, which was organized to market the power, built a wood pulp and paper mill and acquired a pyrrhotite mine as a source of the sulphur needed in the manufacture of pulp. After the sulphur was removed from the pyrrhotite ore, the residue could be smelted to yield an iron containing about 7 per cent nickel. Since there was then no market for such iron, the nickel content had to be reduced. This was done by smelting the residue with iron ore obtained from the Helen mine near Jamestown in the Michipicoten area of northern Ontario.

Several companies participated in the development of the iron and steel industry at Sault Ste. Marie. In 1899 the Consolidated Lake Superior Company was formed to acquire and develop further the local water power and to

operate the Helen mine. A subsidiary company, the Algoma Steel Company, was formed in 1901 to manufacture coke, iron, steel, and steel products. This company built and operated a steel plant which produced steel rails in 1902 before the erection of coke ovens and a blast furnace had been completed at Sault Ste. Marie. The plant contained two 5-ton Bessemer converters with a combined steelmaking capacity of 600 tons a day, a 32-inch blooming mill, and a 23-inch rail mill. On May 5, 1902, the rail mill rolled Canada's first standard rail. In the same year the Algoma Tube Works was incorporated to manufacture tubes, and the steel plant was closed. During 1903 a new company, the Lake Superior Corporation, succeeded the Consolidated Lake Superior Company. It completed its first blast furnace at Sault Ste. Marie in the following year. Before the furnace began operating, it was found that the ore from the Helen mine could yield pig iron more suitable for refining in open-hearth furnaces than in Bessemer converters, and two open-hearth furnaces were therefore installed. Plant facilities were expanded with the construction of new coke ovens in 1906 and 1907 and a second blast furnace in 1908. The entire steel output was in the form of rails, of which 126,775 tons were produced in 1908. In the following year the company began a plant expansion program, including coke ovens, rolling mills, and equipment for making railroad track accessories. The Algoma Steel Corporation, Limited, the third of the leading Canadian iron and steel producers, succeeded the Algoma Steel Company in 1912.

Dominion Foundries and Steel Limited, the fourth principal iron and steel producer, was organized in 1917. Its works in Hamilton, Ontario, produced mainly wrought steel products and steel castings until 1951, when a coke oven plant and a blast furnace began operating.

The Canadian steel industry grew gradually until 1939. From then until Dec. 31, 1952, annual crude steel capacity rose 129 per cent, from 2,094,500 to 4,784,100 tons, and of this capacity, 1,500,000 tons were added in 1950-1952. Annual

Table 3—ANNUAL CAPACITY OF STEEL FURNACES IN CANADA, DEC. 31, 1952

Type of furnace	Number of furnaces	Annual capacity (net tons)

capacity by type of furnace, kind of product, and province on Dec. 31, 1952, is shown in Table 3, and that of the various Canadian steel companies in Table 4.

Total Canadian steel output increased from about 27,000 tons in 1900 to about 970,000 tons in 1911, and to 3,157,867 tons in 1954. (In 1953 a record 4,103,914 tons of raw steel were produced.) Basic data on the primary iron and steel industry as of 1952 are given in Table 5.

Table 5—PRIMARY IRON AND STEEL INDUSTRY IN CANADA, 1952

Province	Number of plants	Number of employees	Salaries and wages (\$000)	Cost of materials at plants (\$000)	Gross selling value of products at plants (\$000)

Total	58	35,001	124,387	239,001	504,002

The rapid growth of the Canadian steel industry has been tempered by the belief that Canada should produce most but not all of its iron and steel requirements. On May 8, 1953, Defense Production Minister Clarence D. Howe stated that Canada then consumed about 5,500,000 tons of steel annually. Concerning the capacity added during 1950–1952, he remarked: "I understand the steel mills would want to absorb that capacity before they move on to another general increase." He concluded: "We have never supplied our full capacity and I do not know it is advisable to do so. It is just as well to have a margin that we import in good times, and do not require to import in poor times—just a little cushion for our

Table 6—CANADIAN IRON ORE DEPOSITS

Deposit and location	Probable magnitude (in net tons)
Quebec-Labrador; a group of deposits between Knob Lake and Lake Ashuanipi on either side of the border between Quebec and Labrador	500,000,000
Ungava; northern Labrador near Ungava Bay, Quebec	566,000,000
Steep Rock Lake; Ontario	100,000,000
Algoma District; North of Sault Ste. Marie, Ontario	300,000,000
Marmora; Ontario	1
Simcoe; near Lake Erie, Ontario	1
Wabana; Bell Island, Newfoundland	3,500,000,000
Quinsam Lake; Vancouver Island, British Columbia	2,000,000

Lake Tio; near Lake Allard, Quebec	4
Sudbury; Ontario	5

¹ The probable magnitude of these and other incompletely developed deposits in Ontario is 200,000,000 tons. ² In 1952 ore conveyers were installed to increase the annual output of this deposit to 2,800,000 tons. ³ An extensive deposit reported in 1951. ⁴ An ilmenite deposit with a probable magnitude of 100,000,000 tons. ⁵ A nickel-bearing pyrrhotite deposit. A process was developed in 1953 to recover 1,000,000 tons of iron minerals annually from pyrrhotite residue remaining after removal of the nickel.

steel industry when it has a rather restricted market."

Iron Ore.—The depletion of high-grade iron ore deposits in the United States led to a search for additional deposits in Canada following World War II. By 1953 two large deposits, Quebec-Labrador and Ungava, were under development. The first large-scale shipment of iron ore from the Ungava deposit, 20,000 tons, arrived by boat at Philadelphia on Aug. 5, 1954. A third deposit, Steep Rock Lake, already producing, was being further developed. It is estimated that these deposits contain a total of more than 1 billion tons of high-grade ore, and that each of them may contain at least 1 billion tons of usable ore. These and others are listed in Table 6. In 1954 a total of 7,280,256 tons of iron ore was shipped from Canadian mines.

MEXICO

The Mexican iron and steel industry might have begun soon after the discovery in 1552 of Cerro de Mercado, the country's so-called iron mountain near Durango, but the Spaniards' successful searches for gold and silver postponed the founding of the industry until the 19th century. Lacking a growing iron and steel industry when the Industrial Revolution began in the 18th century, Mexico remained an importer of iron and steel while other countries, poorer in precious metals, used their industry to provide tools, machinery, equipment, and transportation for industrial expansion. Only during the 20th century has the industry attained significant development in Mexico.

It is estimated that the gold and silver mined in Mexico during the period 1521–1945 amounted to \$3,855 million. In the same period only 1,936,000 tons of iron, 40,667,000 tons of coal, and 35,000 tons of manganese, having a total value of \$149 million, were produced. Had even a small fraction of the gold and silver produced in the 17th and 18th centuries been used to establish an iron and steel industry, Mexico might have become an important industrial nation during the 19th century. In the 20th century the Mexican government has encouraged the development of the industry by waiving duties on imported equipment, granting tax exemptions to Mexican iron and steel producers, and taxing imported semifinished and finished steel products.

Cerro de Mercado Ore.—The ore in Cerro de Mercado is principally hematite, with some martite, magnetite, and limonite. Estimates of the amount of iron ore in the mountain range from 76 million to 200 million tons. The first attempt to use this ore was made in 1828, when a small amount was mined. In 1882 a foundry was built near the base of the mountain by the Iron Mountain Company, which had been organized in the previous year. Ownership of the deposit was transferred successively to the Mexican Iron Mountain Manufacturing Company, the Durango Steel & Iron Company, and, in 1920, to the Compañía Fundidora de Fierro y Acero de Monterrey, S. A., which mined it until 1934. Thereafter, a subsidiary company, Cerro de Mercado, S. A., continued to develop the deposit. From 1920 to 1944 about 2 million tons of iron ore, with an average analysis of 62.0 per cent iron, 3.5 per cent silicon, 0.5 per cent phosphorus, and 0.5 per cent sulphur, were produced from the deposit. Most of this ore was shipped to the parent company's plant at Monterrey.

Steel Production.—Large-scale steel production began in Mexico in 1903 at the Monterrey plant of the Compañía Fundidora de Fierro y Acero de Monterrey, S. A., which had been organized in 1900. By 1953 the company had an annual capacity of 290,000 tons of pig iron and 200,000 tons of crude steel. During 1951 it produced 117,900 tons of finished steel products: rails, joint bars, bars, structural shapes, wire, nails, screws, nuts, and other products.

The second principal producer, Altos Hornos de México, S. A., which was organized in 1942, built a plant at Monclova, Coahuila, and began production in 1944. Its 1951 output of 117,300 tons of finished steel products consisted mainly of tin plate, sheet, plate, and welded pipe. During 1953 construction of an 800-ton-per-day blast furnace was begun. Other Mexican producers and their plant locations are the Compañía de Acero y Maquinaria La Consolidada, S. A., Piedras Negras and Federal District; Compañía Hierro y Acero de México, S. A., Federal District; and Hojalata y Lámina, S. A., Monterrey.

The industry developed in Monterrey and Monclova because of the favorable location of raw materials in the states of Coahuila and Durango; finishing facilities were built in the Federal District, a steel-consuming center; and natural gas from Texas was a factor in selecting Piedras Negras. In 1954, Mexico produced a total of 302,200 tons of iron ore, 217,000 tons of pig iron, and 591,935 tons of steel.

Ore Deposits.—Iron ore deposits occur in Durango, Michoacán, Oaxaca, Colima, Guerrero, and Lower California. Explored deposits are estimated to contain 290 million tons of ore. Fluorspar, manganese ore, limestone, and coal occur in Durango, Coahuila, Chihuahua, and Nuevo León, while mineral deposits suitable for making refractories are located near Monterrey. Coke plants have been built at Nueva Rosita, Palau, and Cloete in Coahuila. To stimulate the production of manganese ore five purchase contracts for a total of 133,500 tons were signed in 1953 by Mexican producers and the United States Defense Materials Procurement Agency. This and other contracts were intended to assure the United States of 550,000 tons of manganese ore for delivery during 1954–1957.

ARGENTINA

The iron and steel industry of Argentina was developed mainly after World War II. Production of finished steel amounted to about 4,500 tons in 1940; that of crude steel, to 339,000 tons in 1954. Plans reported in 1955 anticipated an annual capacity of 1,100,000 tons. Except for local scrap, the principal raw materials are imported.

At San Nicolás on the Paraná River, 37 miles southeast of Rosario, the Sociedad Mixta Siderúrgica Argentina has a blast furnace with a daily capacity of 1,200 tons of pig iron; four 160-ton open-hearth steelmaking furnaces; and rolling mills to produce rails, plates, sheets, structural sections, bars, and tin plate. The only other major steel producer is Acindar Industria Argentina de Aceros, S. A. Its production facilities at Villa Constitución, Santa Fé Province, include a blast furnace rated at 1,400 tons of pig iron daily; four 150-ton open-hearth furnaces; rolling mills to produce concrete-reinforcing bars, structural sections, wire rods, and strip; and a wire mill to produce galvanized wire and nails. At Rosario it has two 35-ton open-hearth fur-

naces with an annual capacity of 60,000 tons and rolling mills to roll concrete-reinforcing bars.

Among other Argentine steel producers are Establecimientos Metalúrgicos Santa Rosa, S. A., located at Tablada, Buenos Aires Province; La Cantábrica Sociedad Anónima Metalúrgica Industrial y Comercial, at Haedo, Buenos Aires Province; Dirección General de Fabricaciones Militares (Board of Military Manufactures), at Zapla, Jujuy Province; and Talleres Metalúrgicos San Martín, S. A., and A. B. K. Electrometalúrgica, both at Buenos Aires.

BRAZIL

In 1935, 52,011 net tons of iron ore, 70,638 net tons of pig iron, and 70,818 net tons of raw steel were produced in Brazil. Thereafter, through the large-scale development of domestic iron ore and coal deposits, plant expansion, and organization of new iron and steel producers, the country's iron and steel industry grew significantly both in output and in diversity of products. In 1954 its output was 1,910,000 tons of iron ore, 1,128,488 tons of pig iron, and 1,256,622 tons of raw steel.

Iron Ore and Coal Deposits.—Brazil's iron ore deposits are believed to be among the largest in the world. It is estimated that the iron ore reserves in the State of Minas Gerais amount to 15 billion tons, of which at least 1 billion are of high grade. Hematite ore is mined at Itabira, 50 miles northeast of Belo Horizonte in Minas Gerais, by the Companhia Vale do Rio Doce, S. A. The company is owned by the Brazilian government, which purchased the Itabira mines from the Itabira Ore Company in 1942. Coal deposits in the states of Santa Catarina, Rio Grande do Sul, Paraná, and São Paulo are estimated to contain 500 million tons, graded from low- to medium-volatile bituminous. Washing the coal yields (1) coal low in ash and sulphur, which can be blended with imported coal to make metallurgical coke, and (2) coal high in ash and sulphur, which is burned to generate steam.

Development of the Iron and Steel Industry.—Financial assistance by the United States government and technical assistance by United States engineers have been important factors in the expansion of the Brazilian iron and steel industry. In 1947 a \$14-million-loan was extended by the Export-Import Bank of Washington to the Brazilian government in order to expand mining facilities, improve the railroad from Itabira to the port of Vitória, and enlarge the ore-loading dock at Vitória. Other loans made by the bank to expand iron and steel production include: \$45 million extended during 1941–1943 to the Companhia Siderúrgica Nacional to build the first large Brazilian steel plant at Volta Redonda; \$25 million to the same company in 1950 to expand its annual raw steel capacity from 343,000 to more than 500,000 net tons; and \$67 million in 1953 to Industria e Comercio de Mineiros of Rio de Janeiro to supply at least 3,850,000 tons of manganese ore containing 45 to 47 per cent manganese to the United States for stockpiling purposes during the period 1956–1962. The last-named loan was intended to develop a 10-million-ton deposit of manganese ore in the Territory of Amapá.

The Companhia Siderúrgica Nacional began operating its Volta Redonda plant, 60 miles west-northwest of Rio de Janeiro, in 1946. It produces coke, pig iron, structural sections, plates,

bars, hot rolled sheets, cold rolled sheets, galvanized sheets, tin plate, and foundry products. The only other large iron and steel producer is the Companhia Siderúrgica Belo-Mineira, which has an annual capacity of 170,000 tons of steel. Plans to expand its capacity to 250,000 tons were reported in 1954. Its plants at Monlevade and Sabará in Minas Gerais produce pig iron, structural sections, plates, rails, bars, wire, and tubular products. The remaining iron and steel plants are located at Santa Barbara, Caeté, Coronel Fabriciano, Esperança, and Gagé in Minas Gerais and in and near the cities of São Paulo and Rio de Janeiro.

CHILE

The large-scale production of iron and steel in Chile began in 1950 with the opening near Concepción of the Huachipato plant of the Compañía de Acero del Pacífico, S. A. The plant's original annual capacity of 236,000 net tons of raw steel was about 10 times the national annual capacity of 1949. The initial plant investment was about \$87 million, of which \$48 million was supplied by the Export-Import Bank of Washington and the Koppers Company of Pittsburgh, Pa. The Huachipato plant was designed to supply domestic requirements and to provide a small surplus for export to Argentina, Uruguay, Bolivia, Peru, and Ecuador. The use of ocean carriers to deliver iron ore, coal, and other raw materials and to take away finished products was an important factor in locating the plant on San Vicente Bay. To withstand earthquakes the plant was cradled in concrete resting on sand, and in April 1949, before it was completed, it survived an earthquake. From July 1950 through June 1951 the plant produced 203,000 tons of pig iron. Its 1952 output of 241,000 tons of raw steel yielded 180,000 tons of finished steel: bars, galvanized sheets, tin plate, and welded pipe. In that year its annual capacity to make raw steel was increased to 260,000 tons; the estimated capacity for 1954 was 440,000 tons.

The Compañía Electro Metalúrgica, S. A., is the only other Chilean steel producer. In 1952 its Santiago plant had an estimated annual raw steel capacity of 3,100 tons and produced forged steel balls for grinding mills, spare parts for mining, agricultural, and manufacturing equipment, and alloy steel castings.

During 1952 the blast furnace at Corral, 190 miles south of Concepción, owned by the Compañía Electro Siderúrgica e Industrial de Valdivia, was operated by the Compañía de Acero del Pacífico. Its annual charcoal pig iron capacity was 29,000 tons in that year. The national pig iron production for 1954 was 333,906 tons.

The principal Chilean iron ore deposits are at El Tofo and El Romeral in Coquimbo Province. National output of iron ore for 1954 was 2,445,338 tons. In 1949 the Bethlehem Chile Iron Mines Company, a subsidiary of the Bethlehem Steel Corporation, contracted with the Compañía de Acero del Pacífico to mine 1,000,000 tons of iron ore a year and to deliver 350,000 tons a year to the Huachipato works; the balance was to be exported. At the same time, the two companies agreed to develop the El Romeral deposit by building a railway and port facilities, Bethlehem contributing \$6,500,000 and Acero del Pacífico \$2,500,000 for the development.

COLOMBIA

In 1953, Colombia had only one steel plant,

which produced steel bars at the rate of about 4,000 tons a year in a rerolling mill at Medellín, Department of Antioquia. In October 1954, a new, large-scale steel plant was opened about 130 miles northeast of Bogotá at Paz de Río, on the Chicamocha River, Department of Boyacá, for the Empresa Siderúrgica Nacional de Paz de Río, S. A. The cost of the plant was estimated at \$120 million, of which \$45 million was supplied by French bankers. Initial annual capacity was 150,000 tons of raw steel.

Iron ore was discovered near Paz de Río in 1942, and by 1952 proven iron ore reserves were estimated at 100 million tons. Both coal and limestone deposits occur within 25 miles of the town, probable coal reserves being estimated to exceed 130 million tons. The coal ranges from high- and medium-volatile to low-volatile bituminous. Extensive coal deposits also occur along the Cauca Valley in western Colombia, near the headwaters of the Patía River, in the Cundinamarca-Boyacá-Santander highlands, in the Department of Santander near the Venezuelan border, and in the northeastern part of the Department of Magdalena. Total national coal reserves, estimated at 12 billion tons, are among the largest in South America.

PERU

In 1955, Peru's first steel plant was being completed by the government-owned Corporación Peruana del Santa at Chimbote, a seaport about 250 miles northwest of Lima. Its equipment was to include two 100-ton Tysland-Hole electric reduction furnaces with a combined annual capacity of 60,000 tons of iron, two 30-ton electric furnaces with a combined annual capacity of 60,000 tons of steel, and three rolling mills. Its principal products were to be concrete-reinforcing bars, sheets for lightweight containers and drums for transporting petroleum.

The iron ore deposits of Marcona, 340 miles southeast of Lima and about 12 miles from the seaport of San Juan, are estimated to contain 170 million tons of probable reserves, and it is estimated that 100 million tons of this ore have an average iron content of 60 per cent. The Corporación Peruana del Santa has begun the development of these deposits by open-cut mining. The first shipments were made in 1953; shipments in 1954 were scheduled at the rate of 200,000 tons a month.

An exploratory drilling program was begun in 1953 by the Republic Steel Corporation on a deposit 37 miles southeast of San Juan and 20 miles from the Pacific Ocean. At Huancavelica, 140 miles east-southeast of Lima, there are iron ore reserves estimated at 70 million tons. Limestone and anthracite coal deposits in the Santa Valley near San Juan are being developed by the Corporación Peruana del Santa. Total national coal reserves are estimated to exceed 4 billion tons.

VENEZUELA

The only steel producer in Venezuela in 1955 was the Siderúrgica Venezolana Sivenso, S. A., which was organized in 1948 and began operating in 1951. Its plant at Caracas contains two electric furnaces which melt local scrap iron and steel and two rolling mills which produce concrete-reinforcing bars. The 1951 raw steel output was about 8,000 net tons, and outputs for 1954 and 1955 were estimated at 15,000 and 20,000

tons, respectively. No blast furnaces had been erected by mid-1955.

Venezuela's iron ore reserves, estimated at 2 billion tons, are in the State of Bolívar. The two major deposits are Cerro Bolívar and El Pao; others are Maria Luisa in the District of Heres; El Trueno, southwest of Cerro Bolívar; and San Isidro, near Cerro Bolívar.

The Cerro Bolívar deposit lies approximately 88 miles southwest of Puerto Ordaz, a port at the junction of the Caroni and Orinoco rivers. About 4 miles long, up to 4,000 feet wide, and averaging 230 feet thick, the deposit comprises the top and sides of a mountain formerly known as La Parida. Its name was changed in 1948 to Cerro Bolívar in honor of Venezuela's liberator. The deposit is estimated to contain at least 400 million tons of high-grade ore, mainly hematite and limonite with a small percentage of magnetite. The average grade reported in 1953 analyzed 58 per cent iron in the natural state, and in the dry state 63.5 iron, up to 0.10 per cent phosphorus, a low percentage of silica, and practically no sulphur.

The development of the Cerro Bolívar deposit necessitated the building of the town of Ciudad Piar at the base of the mountain, a highway extending 80.7 miles from the town to Puerto Ordaz, 91.3 miles of railroad from the deposit to Puerto Ordaz, and an ore-crushing plant, dock, and inland harbor 30 feet deep at Puerto Ordaz; and the dredging of 32 miles of channel 26 feet deep in the 178-mile Orinoco-Caño Macareo waterway from the inland harbor to the Gulf of Paria. A subsidiary of the United States Steel Corporation, the Orinoco Mining Company, began mining the Cerro Bolívar deposit in 1953. The first shipment of ore, comprising 6,700 tons, arrived in Philadelphia on Jan. 19, 1954, en route to the corporation's Fairless Works at Morrisville, Pa.

The El Pao deposit, 36 miles south of San Félix, has measured reserves estimated to contain 72 million tons of iron ore averaging 65 per cent iron. The Iron Mines Company of Venezuela, a subsidiary of the Bethlehem Steel Corporation, began to develop the ore body for open-pit mining before World War II. A 36-mile railroad from El Pao to Palua on the Orinoco River, ore-loading facilities at Palua, a transfer station at Puerto de Hierro on the Gulf of Paria, and three towns for workers were constructed. The first shipment of El Pao ore arrived at Sparrows Point, Md., on March 22, 1951.

Because Venezuela has large petroleum reserves, the search for coal has not been so intensive as that for iron ore. Coal deposits at Naricual in the State of Anzoátegui and at Coro in the State of Falcón are estimated to contain a minimum total of 200 million tons of high-volatile bituminous coal.

IRON AGE. See ARCHAEOLOGY.

IRON CHANCELLOR, an epithet applied to Prince Otto von Bismarck (q.v.).

IRON CROSS. See DECORATIONS AND ORDERS—Germany.

IRON CROWN. See CROWNS AND CORONETS.

IRON CURTAIN, a term applied to the barriers to the exchange of persons and ideas erected by the Soviet Union between its satellites and western Europe. It was popularized following its use in a speech made by Winston Churchill at Fulton, Mo., in 1946.

IRON DUKE, an epithet applied to Arthur Wellesley, 1st duke of Wellington (q.v.).

IRON GATE or **IRON GATES**, a gorge in the Danube River between Orșova and Turnu-Severin, Rumania, on the Yugoslav border, at the western end of the Transylvanian Alps. About two miles long and very narrow, it was so encumbered with rapids that it hindered navigation until a canal was constructed in the 1890's. See also DANUBE.

IRON LUNG. See POLIOMYELITIS.

IRON MOUNTAIN, city, Michigan, seat of Dickinson County, situated at an altitude of 1,160 feet, 48 miles west of Escanaba. It is served by the Chicago, Milwaukee, St. Paul and Pacific and the Chicago and North Western railroads and by North Central Airlines. The trading center for an iron mining and farming area, it has establishments producing chemicals, clothing, and automobile parts. A large ski slide attracts many winter visitors. Settled in 1879 and incorporated in 1889, the city is governed by a mayor and council. Pop. 9,299.

IRON MOUNTAIN, peak, Missouri, the southern spur of the St. Francois Mountains, a low range in the eastern part of the state; altitude 1,077 feet. This mountain, which is really a hill or knob, is in St. Francois County, 38 miles west-southwest of St. Genevieve, the nearest point on the Mississippi River, on the Missouri Pacific Railroad. Its area is 500 acres.

Iron Mountain is famous for its remarkable deposit of hematite iron ore, the purest in the United States. Excavations were begun in 1845. An artesian well was sunk to the depth of 152 feet, with the result that the beds passed through from the surface were as follows: Iron ore mixed with clay, 16 feet; sandstone, 34 feet; magnesian limestone, $7\frac{1}{2}$ inches; gray sandstone, $7\frac{1}{2}$ inches; hard blue rock, 37 feet; pure iron ore, 5 feet; porphyritic rock, 7 feet; iron ore, 50 feet to the bottom. It would seem that nearly the whole mountain was a mass of magnetic iron ore. The adjacent valleys are underlaid with magnesian limestone in horizontal strata. Pilot Knob, about six miles south of Iron Mountain, also contained an extensive deposit of iron ore; Shepherd Mountain, a short distance southwest of Pilot Knob, is the largest of the iron mountains in the immediate vicinity. The Cerro del Mercado near Durango, Mexico, is another famous hill of iron.

IRON RIVER, city, Michigan; in Iron County, on the Upper Peninsula, 34 miles west-northwest of the city of Iron Mountain and 5 miles from the Wisconsin border; altitude 1,490 feet. It is a trading center for an iron-mining, lumbering, and agricultural region, and is served by the Chicago and North Western and the Chicago, Milwaukee, St. Paul and Pacific railroads. Settled about 1881, it was incorporated as a village in 1885 and as a city in 1926. Pop. 3,754.

IRONBARK, a name of several eucalyptus trees, the bark of which (except for *E. leucosylon*) is persistent, rather than deciduous as with other eucalypti. In general the hardness of their wood makes the ironbarks highly prized for ship-building and underground construction. *Eucalyptus paniculata* (white or red ironbark), the hardest of the ironbarks, has grayish brown bark, and wood which is generally pale in hue; *E. melanophloia* (silver-leaved ironbark), is a small tree, with dark, furrowed bark; *E. siderophloia* (broad-leaved ironbark) is tall, and much planted in the San Joaquin Valley, California; *E. crebra* (narrow-leaved ironbark) has reddish wood, is frost-resistant, and is found in many parts of California. Other ironbarks are *E. leucosylon* (white ironbark), bark deciduous; and *E. siderosylon* (red ironbark). Originally Australasian, like other eucalypti the ironbarks have been spread to most of the warmer parts of the world.

IRONCLAD OATH, The, an act passed by the United States Congress, July 2, 1862, requiring every federal office holder, civil or military, to swear allegiance to the Constitution and declare that he had never voluntarily borne arms against the United States. It was used to debar Southerners from office.

IRONDEQUOIT, à-rôn-dî-kwoit', town, New York; in Monroe County; bounded on the south by the city of Rochester. Chiefly a resi-

dential community and summer resort, it is situated on Irondequoit Bay and Lake Ontario.

In 1718 Jacques René de Denonville built the Fort des Sables on a sandbar in Irondequoit Bay, following visits by French explorers, notably Robert de La Salle in 1669 and 1678. First settled in 1791, Irondequoit was incorporated March 27, 1839. Government is by supervisor and council. Pop. 55,337.

IRONTON, i'ern-tûn, city, Ohio; seat of Lawrence County; altitude 540 feet. It is situated on the Ohio River, 93 miles south-southeast of Columbus, and is served by the Detroit, Toledo and Ironton and the Norfolk and Western railroads. Industrial production includes malleable castings, coke, graphite products, portland cement, chemicals, construction steel, electrical equipment, automobile parts, dry pressed brick, quarry tile, and stoves. The city has considerable river commerce; a bridge over the Ohio enables shippers to connect with the Chesapeake and Ohio on the Kentucky side. It has an airport, with airline service. There are three hospitals, one of which is a county institution.

The wealth of iron ore in this part of Ohio began to be exploited in the 1820's. John Means, of Virginia, made pig iron, with a charcoal furnace, here in 1826. In 1834 John Campbell experimented with new methods, and was so successful that the industry became firmly established here. He founded Ironton; it was incorporated in 1849. But the iron and steel industry shifted to other regions, and the furnaces have been supplanted by factories. The city government is administered by a city manager and council of seven. Pop. 15,745.

IRONWEED, in the United States the popular name for a genus, *Vernonia*, of tall, coarse, composite plants, several species of which grow abundantly in woods and along roadsides throughout the eastern and southern parts of the country as far west as Kansas and Texas. They bear heads of magenta-colored flowers somewhat like miniature thistles.

IRONWOOD, city, Michigan; in Gogebic County; altitude 1,505 feet. It is situated on the Upper Peninsula, on the Montreal River, opposite Hurley, Wis., and is served by the Chicago and North Western and the Soo Line railroads. It is the trading and shipping center of the Gogebic Range, rich in iron ore and timber. There is also dairying and truck farming in the area. The city has planing mills and manufactures of dairy and meat products. It is the seat of Gogebic Junior College (coeducational), a municipal institution founded in 1932.

Iron ore was discovered here by J. L. Norrie in 1884. The town was laid out and the railroad built to the site in the following year. Two years later it was incorporated as a village and received a city charter in 1889 and has city-manager government. Pop. 10,265.

IRONWOOD, a popular name for many trees whose timber is very hard and heavy. Probably the best known species in America is also known as leverwood, *Ostrya virginiana*, of the family Betulaceae, indigenous from Nova Scotia to Florida and westward to Minnesota and Texas. It is a medium sized tree with furrowed bark, birch-like foliage, pistillate flowers in catkins resembling the female flowers of hop,

hence its popular name, hop hornbeam. *Carpinus caroliniana*, the hornbeam (q.v.), is also sometimes called ironwood. Common Asian ironwoods are *Mesua ferrea*, often planted around Buddhist temples for its fragrant flowers, and *Metrosideros vera*, the iron tree of Java. Australian species include members of the genera *Olea*, *Melaleuca*, *Notelaea*, and *Myrtus*.

IROQUOIAN FAMILY, ȳr-ô-kwoi'ân, a linguistic stock of North American Indians whose ancestral home was in what is now the southern United States. Their name, which was given originally by the French to the League Iroquois, was subsequently extended to include the entire stock. The following groups are classified as Iroquoian: Huron (Wyandot); Tionontati (Tobacco); Neutral; Erie; Wenrohronon; Susquehanna (Andaste or Conestoga); Nottoway; Meherrin; Cherokee; and the Iroquois League (Mohawk, Oneida, Onondaga, Seneca, Cayuga, and Tuscarora).

When first encountered by white men, the Iroquoians lived as isolated groups among Algonquian, Siouan, Muskogean, and Uchean peoples. The problem of their dispersion and historic locations remains unsolved. The first contact with an Iroquoian people was made by Jacques Cartier, on the Gaspé Peninsula in 1534. (These Iroquoians were assimilated by their neighbors, for Samuel de Champlain found no trace of them 70 years later.) In 1540, Hernando de Soto discovered the Cherokee in eastern Tennessee and adjoining parts of Georgia and Carolina. Capt. John Smith was the first Englishman to contact an Iroquoian group, the Susquehanna, on Chesapeake Bay in 1608. In the following year, the Dutch discovered the League Iroquois between the Hudson and Genesee rivers, territory which they occupied until the close of the American Revolution.

The Iroquoians banded together in confederacies for mutual aid. Women were important: chiefs were nominated and retained title by female consent; women controlled land and all property except personal effects; and their communal gardens provided staples. Bark houses were large enough for several families, and early villages were fortified with stout palisades.

Except for the League Iroquois, only the Cherokee and the Huron-Wyandot survive. The others were defeated, dispersed, or assimilated by league members. The Cherokee now live in Oklahoma and North Carolina; the Huron, in Oklahoma and at Loretteville, Quebec, Canada.

See also SIX NATIONS OF THE IROQUOIS; separate articles on the various tribes.

GEORGE S. SNYDERMAN.

IROQUOIS LEAGUE, ȳr-ô-kwoi, the name given by the French and their Algonquin allies to the Five (later Six) Nations Indians of North America, the word *Iroquois* being a Gallicized form of *Irinakhoiw*, an Algonquin word meaning "real adders." These people called themselves Ho-de-no-sau-ne, meaning "long house building residents." The analogy of the long house was transferred to their political thought, and the member nations were considered brothers living in a house with five fires or rooms. The eastern door of the house was near Schenectady, N. Y.; the western door was the Genesee River; and the north and south walls were the St. Lawrence and Susquehanna rivers, respectively.

The Mohawk were the eastern doorkeepers; the Seneca, the western doorkeepers; the Onondaga, the keepers of the central fire. The Oneida and the Cayuga "sat along the north and south walls," respectively. The Tuscarora were admitted in 1722; they were "adopted" by the Oneida and therefore sat with them. Although they were allowed to sit in the Federal Council, they were never awarded league titles—that is, they were given membership without voting privileges.

The league was formed in the mid-16th century by Dekanawida and his assistant, Hiawatha. According to tradition, Dekanawida was born of a Huron mother in a village on the northeastern shores of Lake Ontario. After he had failed to persuade the Huron, Erie, Neutral, and other cognate tribes to adopt his plan for peace, he tried with the assistance of Hiawatha, a Mohawk, to convert the Onondaga. Failure forced the two men to take their message to other tribes. The Mohawk, Cayuga, and Oneida joined immediately, and the Onondaga and Seneca later on. The success of Dekanawida and Hiawatha was due to their political astuteness, personal characteristics, and the timeliness of their philosophy. Their plan was also acceptable because it allowed local autonomy. Theoretically, the league was one large family whose members lived in peace. Actually, it was a confederation of Indian villages whose chiefs constituted the Federal Council. The *Epic of Dekanawida* lists the founders in the order in which they accepted the plan. These names are now hereditary titles and are recited as part of the condolence ceremony when new chiefs are elevated.

Villages or tribes affiliating after the initial adoption of the Iroquois Constitution were allowed to speak but not to vote. Tribes were unequally represented in the council: the Mohawk and Oneida each had 9 chiefs; the Onondaga, 14; the Cayuga and Seneca, 8 each. The Cayuga and Oneida (younger brothers) and the Seneca and Mohawk (older brothers) caucused as separate units, while the Onondaga sat as impartial chairmen. Since each tribe voted as a bloc and unanimity was the rule, no tribe or group of tribes could dominate the league. A league chief held office for life or for as long as he performed his duties with devotion and honesty. Nominated by the matrons of the family holding the title, he was then elected by the village and raised to the Federal Council by the condolence ceremony. A crown of antlers symbolized both the office and peace. Chiefs wishing to go to war required permission from the council.

A chief was obligated to attend council meetings whenever he was summoned. He could be impeached for persistent absence from meetings, idle gossip, dishonesty, ambition to establish an independent authority, murder, and other offenses. The title was then given to another family, for the entire family was held responsible for the chief's behavior. Charges against a delinquent chief could be instituted by any adult. Failure to heed three warnings automatically resulted in his dismissal, and acceptance of the demotion by the league was perfunctory. Titles were loaned to other families when no suitable candidates existed.

War chiefs of the league led no armies, for the league had no constabulary: as a body it never declared war. Peace between league members was promoted by arbitrating local differences, but since the league freed its members from fear

of attacks by other members, it actually encouraged war on outsiders.

Shortly after the first quarter of the 17th century, league members quickly subdued the neighboring tribes of New York, New England, and Pennsylvania. They then turned their attention to the Algonquin, Huron, Tionontati, Neutral, Ottawa, Illinois, Erie, Susquehanna, Tutelo, and Catawba, but failed to conquer the Ojibwa in the West and the Cherokee in the South. Colonial governments found it profitable to deal with Onondaga, the capital of the league, for here were to be found ways and means of legalizing transactions—that is, war, peace, and land sales. These transactions were sometimes unacceptable to individual nations or villages, and the league found it increasingly difficult to control recalcitrants or to obtain general agreement on important issues. The political importance of the league finally ended when the federal chiefs bartered away the lands and sovereignty of their people for the brandy and bribes of the whites.

In the wars between the British and the French, which continued intermittently until 1763, the Iroquois fought for both sides. Some Mohawk Roman Catholic converts, for example, seceded from the league and were settled by the French in Quebec at St. Régis or at Caughnawaga. Other Mohawks, under the influence of Sir William Johnson, fought with the British. The league remained neutral in the American Revolution, but all the tribes participated, most of the Oneida and Tuscarora favoring the colonists. After the victory of the colonists, Joseph Brant led many of the defeated Iroquois to Canada, where they were given land by the crown. The Cattaraugus and Allegany Seneca seceded from the league after the Treaty of Buffalo Creek (1802). Only the Tonawanda Seneca and the Onondaga continue to adhere to the league politically.

Handsome Lake, the Seneca prophet, embodied the organization and many of the principles of the league in his religious teachings. The non-Christians who are his followers meet regularly to observe and discuss these principles. The Iroquois Constitution impressed and influenced the political philosophy of Benjamin Franklin, George Washington, and other founding fathers of the United States. Many of its principles were woven into the United States Constitution.

For social, economic, and other aspects of the Iroquois, see *SIX NATIONS OF THE IROQUOIS*; also separate articles on the individual tribes.

GEORGE S. SNYDERMAN.

IROQUOIS TRAIL, a main trail of the confederacy of the Five Nations of the Iroquois, established long before the white man trod New Netherland soil early in the 17th century. It began at the Hudson River on the site of Albany and ended at Lake Erie on the site of Buffalo. The Iroquois called it "Wa-a-gwen'-ne-yu," and the French Jesuit missionaries named it "The Beaten Road." From the site of Albany the path struck northwestward to the first of the Mohawk "castles" on the Mohawk River at Schenectady. Starting at the ford there, the trail continued upstream on both banks, the right-bank trail being most traveled because the Mohawk castles were on that side. This central Iroquois trail continued through Oneida country to the Onondaga Valley and the capital of the confederacy at Onondaga. After leaving Onondaga territory it

passed through Cayuga country to the valley of the Genesee River, heart of the Seneca lands, and so to Lake Erie.

IRRADIATION, ĭ-rā-dī-ă'shŭn, in optics, an apparent enlargement of a bright body when seen against a background darker than itself. This effect has been ascribed to the excitation of retinal cells just beyond those directly affected by the light, to defects in the human lens, and to light aberration by the atmosphere. Its chief practical effects have been in astronomy, where irradiation has made it difficult to measure planetary diameters with precision, has distorted the shape of the cusps of crescents, and, during eclipses, has enlarged Bailey's beads (the last points of light from the sun, shining through the unevennesses of the moon's surface).

ISAAC ASIMOV.

IRRADIATION, in physics, the exposure of any object to the influence of radiation, either electromagnetic or particular in nature. The term is used most commonly where radiation more energetic than that of visible light is involved. Irradiation can be cosmetic in purpose, as when ultraviolet light, originating in either the sun or in a mercury-vapor lamp, is used to induce a tan. It can also be therapeutic, as when ultraviolet light is used to treat skin disorders, or when X-rays or gamma rays are used to destroy malignant tissue.

Irradiation by ultraviolet light is capable of bringing about important chemical changes. Most notably, ring B of the molecules of certain steroids is ruptured with the production of compounds with vitamin D activity. In the layers beneath human epidermis, 7-dehydrocholesterol is present, and this is converted by solar ultraviolet light to cholecalciferol (vitamin D₃). This gives rise to the popular term, "sunshine vitamin" for vitamin D. Foods such as bread and milk contain steroids which can undergo similar changes, and it is common to enrich foods in this respect by irradiation.

Irradiation by X-rays or gamma rays can be deadly, and where destruction is desired, as in the case of malignant tissue, this is a useful fact. Gamma rays can be used to destroy insect eggs and to sterilize adult insects in raw foodstuffs such as grains and spices. This introduces a method of insect control which may eventually supersede chemical methods. Irradiation is more effective on eggs than are chemical insecticides, and it is more difficult for adult insects to develop resistance to gamma radiation than to chemicals. Furthermore, irradiation leaves no residue of potential harm to domestic animals or to humans.

Irradiation by gamma rays or by high-energy particles can also destroy bacteria in food within a sealed container. This opens the possibility of sterilization without heat or evacuation, so that food in plastic containers, rather than in the more expensive metal cans, may some day be stored at room temperature indefinitely.

Industrially, irradiation by gamma rays and high-energy particles has numerous uses. For instance, it can be used to bring about chemical changes in plastics, leading to sometimes desirable alterations in properties.

H. Cartier-Bresson from Magnum

In the delta of the Irrawaddy, the river teems with small-boat traffic.

Irradiation can be measured as the radiant power (in watts) per unit area. This is called "specific irradiation" or "irradiance." The "total irradiation" is the irradiance multiplied by the total area of the object being irradiated.

School, Boston University.

IRRATIONAL NUMBERS, *ir-rāsh'un-āl*, numbers that are not integers or fractions (natural or rational numbers); numbers that are incommensurable with unity. Generally such numbers arise in the processes of mathematical operations, such as the extraction of roots and the solutions of equations. They cannot be represented exactly either as sums, differences, products, quotients, or integral powers of natural numbers (repeating decimal fractions arising in divisions, such as $2 \div 7$ or $3 \div 13$, are not included). Thus $\sqrt{2} = 1.4142 \dots$ is an irrational number. An irrational number contains a decimal part in which the sequence of the digits does not exhibit any known or hidden regularity.

The ratio, π , of the circumference of a circle to its diameter is a special type of irrational number, known as a *transcendental*. The approximate value, $\pi = 3.14159 \dots$, has been computed electronically to more than 2,000 decimal places. The values of logarithmic and trigonometric functions are also transcendental. The Russian mathematician Izrail M. Gelfand (1913-) has demonstrated that any rational number raised to an irrational power results in a transcendental number. Thus $3^{\sqrt{2}}$ is transcendental.

The German mathematician Richard Dedekind (1831-1916) suggested the representation of an irrational number in terms of a "cut" of two sequences of numbers: one contains values all less

than the value of the irrational, while the other contains all values greater than the value of the irrational. But the irrational number itself does not belong to either of these two sequences. Thus $1.4142 \dots < \sqrt{2} < 1.4143 \dots$

York University.

IRRAWADDY RIVER, *ir-ā-wōd'ī* (sometimes IRAWADI), river, Burma, running from the extreme north of the country generally southward to the Andaman Sea. Its sources are two rivers, the Mali Hka (west) and Nmai Hka (east), which rise in Kachin State near the border of Tibet and run parallel southward to unite above Myitkyina ("near great waters"). From Myitkyina to Bhamo (91 miles) the river is navigable to steamships during the low-water season (October-February); in this stretch its width is about 900 yards. Just north of Bhamo the river bores its way through the hills in what is called the First Defile. The hillsides are steep, the width closes in to 100 yards, and the depth exceeds 30 fathoms. After the monsoon the river rises 50 feet or more in this defile, preventing navigation.

Just below Bhamo the river enters the Second Defile; it broadens out again, then after about 90 miles enters the Third Defile, which continues for 20 miles but is much wider and does not produce such a strong current as the higher defiles. From Bhamo to Mandalay is 275 miles, and from Mandalay to Rangoon, the capital, is 597 miles. Eighty miles below Mandalay the river is joined by the Chindwin River, which is almost as long and wide as the Irrawaddy. The

river is now a mile wide in places, creating great bends, with mud banks that are islands except during floods.

In its lower reaches in the delta the river becomes a maze of meandering tidal creeks, draining into the sea through 10 main channels. The Rangoon River is not actually an effluent of the Irrawaddy, but Rangoon is joined to the main stream 22 miles to the west by the Twante Canal, navigable by large river steamers. The total length of navigable water (Bhamo to the sea) is approximately 900 miles. The river is spanned by one bridge only, the Ava Bridge, just below Mandalay, which carries road and rail.

Economic Importance.—The Irrawaddy is the main artery of Burma. River steamships are operated by the state Inland Water Transport Board, but about half the traffic is carried in private boats, propelled by sail and oar. From the forests of the north, and from around the Chindwin, come great "rafts" of thousands of logs chained together. Oil from Chauk is carried down to the Syriam refinery, opposite Rangoon. From all over the delta comes the rice crop. Every few miles up the river are little market towns, some with a specialty—for example, Shwegu (pottery) or Pagan (lacquer ware). The total volume of trade carried is about equal to that of the railroad system running southward to Rangoon. Navigation, however, is much more hazardous than formerly. During the Japanese invasion of 1942, the steamer fleet was taken upriver and deliberately sunk, as a barrier, just south of Mandalay. In 1961 many ships still remained there, half submerged.

History.—Most of the history of Burma relates to the Irrawaddy. In the extreme north, the watershed between the eastern source of the river (Nmai Hka) and the Salween River in China was regarded by the government of Burma, both before and since independence, as the "natural" frontier between Burma and China. This claim was long disputed, but in January 1960 Communist China at last recognized it. During the 1880's and 1890's, China had laid claim to Bhamo as a "free port" on the Irrawaddy. Bhamo, 30 miles from the frontier, is the main outlet for trade between the Chinese Province of Yunnan and Burma. The claim was rejected, though Bhamo remained a community of Chinese. Eight former capitals lie on or near the river. The most northern is Tagaung, followed by Shwabo, and then (all near together) Mandalay, Amarapura, Ava, and Sagaing. From 1364 to 1885, though the actual site was often changed, the capital stood just above the great westward bend of the Irrawaddy near Mandalay. Over 100 miles downriver stands Pagan (capital, c. 1050-1287), and 160 miles lower still is Sri Ksetra or Old Prome (capital, 638-832).

Reader in Oriental History, University of London.

IRREDENTISTS, ır-ê-dên'tists, members of an Italian nationalist movement for the annexation to Italy of territories—*Italia irredenta* (unredeemed Italy)—inhabited mainly by Italian-speaking people, but remaining under foreign rule after 1866. The phrase *Italia irredenta* was first used by Matteo R. Imbriani in Austrian-held Trieste in 1877. "Irredentism" has often been used also to describe nationalist agitation in other countries for the incorporation of terri-

tories that remain subject to foreign rule.

Italian irredentism was an extension of forces set in motion during the Risorgimento, culminating in the wars of Italian unification (1859-1866). The unification of Italy had been achieved at the expense of Austrian territorial possessions and influence in the Italian peninsula. Since Austria continued after 1866 to rule several Italian-inhabited areas claimed by Irredentists, it was the main target of Irredentist agitation.

Associations for *Italia irredenta* were first formed in 1877 under the leadership of Imbriani, Giuseppe Avezzana, Giovanni Bovio, Luigi Zuppetta, Roberto Mirabelli, and others, with the support of Giuseppe Garibaldi, Federico Campanella, Giosuè Carducci, and other ex-Garibaldians. The various Irredentist groups within Italy and beyond its frontiers were by no means in accord regarding their objectives. For some organizations the goal was limited to those Italian-speaking territories north and east of Italy under Austrian control (Gorizia, Trentino, Istria, and Trieste). Other, less numerous Irredentist groups pressed for the redemption of Corsica and Nice, which formed part of France, and of British-held Malta. Moreover, even those who focused their efforts on Austrian-held territories disagreed on whether to extend (for strategic reasons) the northern frontier to the Brenner Pass, which meant absorption of many German-speaking people. The question of methods to obtain these objectives further divided the movement between those in favor of peaceful solutions and those urging war if necessary. The division of effort and lack of a common program were even more evident among Irredentists living under Austrian rule. Many of them made it clear that they were concerned only with the Austrian-controlled area in which they lived and not with other Irredentist territories. Generally, the immediate objectives of Italians under Austrian rule were more educational privileges and greater political autonomy.

Despite internal divisions, the Irredentist movement was a significant force in Italian politics, particularly as it affected foreign policy, from 1877 to World War I. During the last two decades of the 19th century, Irredentist activity was frequently repudiated by the Italian government, which feared that it would endanger Italy's efforts to strengthen ties with Austria and Germany through the Triple Alliance. The gradual shift in Italian foreign policy which produced a rapprochement with France after 1900 diminished the pressure of official disapproval.

Italy's entry into World War I on the side of the Allies was in part the result of organized pressure by Irredentists, among whom Gabriele D'Annunzio was a prominent figure. Italy's territorial gains at the Paris Peace Conference of 1919 fulfilled the hopes of most Irredentists and brought the movement to a climax. Nevertheless, residual problems remained, and it was not until 1954 that Italy and Yugoslavia reached a settlement on Trieste.

IRRIGATION, ĩ-ĭ-gā'shūn, the watering of land artificially in order to produce crops. In the simplest cases water is drawn from a well or a stream and is poured into a small ditch from which it runs over the land. This is practiced by single farmers or by small groups in arid countries all over the world. Larger communities need more complicated systems, in which rivers supply canals and these subdivide into branches which carry the water to all parts of the cultivated areas. The largest systems involve the development of entire river basins by means of great engineering works, canals, regulators, and dams.

The largest irrigated areas are to be found in India, China, western United States, the USSR, Egypt, Iraq, South Africa, southern Europe, Australia, and South America. The area is continually expanding.

Ancient Irrigation.—Irrigation began as a natural phenomenon in places like Egypt and Mesopotamia, where there is almost no rain but the rivers rise in flood every year and in prehistoric times inundated large areas along their banks. When the floods subsided, seeds were planted in the mud, and crops matured on the water left in the soil. The first artificial irrigation probably began by taking water from the pools which remained in depressions for months after the flood water had retreated, and this led to the invention of primitive lifting machines like the Egyptian shadoof (denkli or paecotta in India). It also led, where conditions were favorable, to the damming of the exits of depressions with stones and earth in order to hold up a bigger supply of water for later use. It is a tradition that Menes, the first king of unified Egypt (fl. about 3100 B.C.), built banks to control the Nile and so originated the basin system of irrigation which continues to this day in the southern part of Egypt. At any rate, there is no doubt that irrigation was practiced in Egypt long before historical times, which date between 4000 and 3000 B.C. Traces of ancient canals still remain also in Iraq, and there are traditions of works

carried out by Nimrod (fl. perhaps about 2450 B.C.).

The flood of the Nile was always a dominant factor in the life of Egypt. Even in ancient Egyptian times there were Nilometers or scales for measuring the height of the river, and the ruins of some of these still exist. A later one on Roda Island, Cairo, dates from about 711 A.D. and was in use up to the 20th century, when extensive repairs were necessary. The well and the pillar on which the scale stands were later shut off from the Nile and surrounded by a concrete curtain, so that the Nilometer would remain indefinitely as the oldest Arab monument in Egypt.

Records of flood levels on this Nilometer and on one of the earlier devices go back with breaks to 622 A.D.

Primitive machines, dating from ancient times, are still in use in the East for lifting water. One is the *shadoof*, consisting of a long arm pivoted between two posts. The shorter part of the arm carries a weight of stone or a ball of clay, and the longer part a rope or long stick to which a bucket is fastened. This is set up beside a pool, water-course, or well. The worker pulls the longer arm down until the bucket dips into the water, and then, assisted by the counterweight, lifts the full bucket and pours the water into the ditch, which carries it onto the land. Sometimes shadoofs are used in series one above another.

Another contrivance, for use where the lift is small, is the *Archimedean screw*, which consists of a wooden cylinder with a helix inside and an axis at both ends (or alternatively a helix twisted around a cylinder). It is mounted on posts with one end dipping into the water, and a crank on the upper end of the axis is turned by one or two men sitting in the water, so that water rises in the helix and flows out at its top. The *sakieh* or *Persian wheel* consists of a vertical wheel on a horizontal axis with a series of pots round its rim. Attached to this axis by a shaft is a toothed wheel into which a horizontal toothed wheel gears. A cow, buffalo, or camel, attached to this horizontal wheel by a shaft, turns it by walking in a circle. As the wheel turns, the pots dip into the water, fill, and when they reach the top of their circle, empty the water into a trough and so into a field ditch. If the water is low, the pots are fastened to an endless rope which passes over the wheel. A modern development of the *sakieh* can be seen in Thailand, where a windmill is used to turn the wheel which carries the string of pots. The shadoof is much earlier than the Archimedean screw or the *sakieh*, and there are pictures of it on ancient Egyptian monuments, where scenes relating to irrigation occur in very early times.

MODERN IRRIGATION PRACTICE

Flood and Perennial Irrigation.—Irrigation on a large scale is practiced only on fairly flat ground, such as the flood plains of rivers. In this there are two general systems: irrigation only when the river is in flood; and perennial irrigation. In Egypt, in flood or basin irrigation, as it is called there, the narrow strip along the Nile, bounded by desert hills on either side, is divided into basins of 1,000 to 40,000 acres by cross banks from the river to the desert. Water is admitted into these basins by canals through the longitudinal bank along the river when the river rises in flood. The water remains

In Egypt, a cow turns a *sakieh* or *Persian wheel*, a primitive irrigating device used since ancient times.

Citiles Service Company

on the land for several weeks and is then run off by escapes into the river, which by this time has fallen.

In modern Egypt only about one sixth of the cultivated area remains on the basin system; the remainder has been converted to perennial irrigation. In perennial irrigation, water is given at suitable intervals throughout the year. In large-scale irrigation it is brought from a river by main canals to branch canals and then to smaller canals which feed the permanent channels by which water is brought to the individual fields. As the river supply is usually variable, reservoirs are necessary to make the most of it by storing water from times of high supply to times of low supply.

Distribution Methods.—When the water reaches the field, there are two principal types of distribution: *flood irrigation*, in which the area is divided into compartments with fairly flat surfaces and water is run on to cover the whole of the surface; and *furrow irrigation*, in which the land is laid out in ridge and furrow and the water is run into the furrows and does not cover the whole surface. Grain and forage crops are usually flooded, while cotton, maize, potatoes, sugar beet, and most crops grown in rows are watered by furrows. The same piece of land is often used for either type of distribution, and on the same farm some will be under flood and some under furrow irrigation.

In one layout for flood irrigation, a field is divided into small basins or checks by ridges (or levees) and field ditches, and each basin is flooded from a field ditch. Where the field is not very level, the ridges may approximately follow the contours, and the field ditches follow the gradients. In another layout the field may be divided by broad ridges into long, narrow strips sloping away from the field ditches, so that the slope across the strip is small. The

water flows in from the ditch at the top end of the strip and slowly makes its way to the bottom end, wetting the whole strip as it travels. This is known as border strip flooding.

In furrow irrigation, the furrows usually run down the steepest slope away from the field ditch. They vary in length, up to a quarter of a mile. The spacing of the furrows is arranged so that the plants are on the ridges with the furrows between them, with distance between the rows suitable to the plants. Two rows of plants may be on one ridge. In watering, a small opening is made through the bank of the ditch, and the water is allowed to flow into one or more furrows. Below the opening, the ditch is dammed, sometimes with earth taken from the cut in the bank and sometimes with a portable dam of wood, steel, or canvas.

In more recent times irrigation by *sprinklers* has come into use, and portable systems have been devised with aluminum pipes and couplers. The pressure needed can in some circumstances be produced by gravity, but usually a pump is needed. Sprinkler systems are satisfactory where the land has an irregular surface or would be

Aluminum Company of America

A sprinkler system of aluminum piping is used to irrigate a large cultivated area.

difficult to irrigate by surface methods. They are also suitable where the soil is very permeable and has a small capacity for holding water, so that it needs light waterings at short intervals, or where the water table is high.

Crop Requirements.—An important quantity in irrigation practice is the amount of water required to grow crops. This varies with the crop, the nature of the soil, the temperature, humidity, and rainfall. In some places—for example, Egypt and parts of the United States—the rainfall is negligibly small so that all the crop requirements must be supplied by irrigation. At the other extreme are places with a fair but capricious rainfall, where a little irrigation at the right times can improve crop yields considerably. Such areas exist in many parts of the world—for example, in America, East Africa, and even in the southeast of England.

In addition to the requirements of the crop plants, allowance must be made for evaporation losses from the soil, transpiration from weeds, and in large irrigated areas for transmission losses from canals and reservoirs. When water is available, farmers usually tend to give more than the economical amount on which crops can be grown. Most crops show a certain amount of tolerance, however, and variations of 10 per cent from the optimum cause only small variations of yield.

Regulators span an irrigation canal near Yuma, Arizona.

Lanks from Monkmeyer

A great deal of research on water requirements in relation to climatic conditions, nature of soils, and subsoil water levels has been carried on all over the world. In Egypt, cotton during its growing season requires about 3 feet depth of water in Lower Egypt and more in Upper Egypt. Rice, which grows in water, requires about $2\frac{1}{2}$ times as much as cotton. In South Africa, grain crops can usually be grown with 15 inches depth of water. In the western United States the water requirements for cereals (excluding rice), sugar beets, cotton, and potatoes, vary for a single crop from 1 foot to $3\frac{1}{2}$ feet depth of water including rainfall. Alfalfa and forage crops require more water than the preceding, averaging about 3 feet. In very hot, dry regions these figures are exceeded. Rice requires from 4 to 10 feet.

Canal Systems.—The perennial irrigation of large areas requires a river as the source and a canal system as a means of distributing the water. The system usually consists of main canals taking directly off the river, branch canals or laterals, and distributaries from which water is turned into the permanent ditches which serve large farms or groups of small farmers. In order that the level in the canals may be high enough to allow a free flow of water onto all the land to be served, and also that each canal may receive its proper share, a system of regulating works is necessary. On the river below the offtake of a main canal, a barrage or diversion dam is built. It usually consists of a masonry work like a bridge, and contains enough sluices to pass the whole discharge of the river in flood; or part of the flood discharge may be carried by a spillway. Above this barrage are the head regulators of the main canals, which take off the river at this point which are similar to the barrages, with sluices. By manipulating the sluices in the barrage and in the canal head regulators, the river is kept at a suitable level, and each canal receives its proper share of water. Regulators on a main canal enable the branch canals to receive their shares, while single sluices control the supply to farm ditches.

Economical and fair distribution depends on careful measurement of the water in the river and in the canal system at all salient points. With good design and test measurements of the flow through the sluices, a regulator can be converted into a water meter. After these measurements, the discharge can be calculated from the

number of sluices open and the amount of opening, combined with the levels upstream and downstream of the regulator. The canals are designed according to the areas which are dependent on them, and the distributaries are worked on a timetable so that the main and branch canals run steadily and the water is evenly distributed over the area.

Storage Reservoirs.—The flow of most rivers is variable. As long as the demand for water is below the minimum discharge, this variability does not matter; if it increases beyond the minimum, storage from times of plenty is necessary to make up deficits that occur when the river is low.

A storage reservoir is made by building a dam across a river at some suitable site which provides a good rock foundation and a large capacity above the site. The sluices and spillways in the dam enable the river discharge issuing from the reservoir to be controlled so that excesses over requirements can be stored and later deficits made up from storage. Water not required for irrigation is allowed to flow over the spillways at the sides of the dam or through valves to the river below.

Where the rainfall has a seasonal distribution, the rivers have an annual regime, and this leads to a fairly regular annual procedure of filling reservoirs in floodtime and emptying them when the river is low. The need has become apparent in some cases for a further stage in storage, namely, overyear storage from good years to bad years, and this point has been reached on the Nile.

Drainage.—All water used for irrigation contains mineral matter in solution. Consequently evaporation from land cultivated by irrigation tends to concentrate these mineral salts in the surface soil. To avoid this, it is necessary to have drainage so that water can percolate through the soil and dissolve out concentrations of salts. The fields are drained by small ditches or tile drains, which run into collector drains that are usually parallel to and between the tributary canals. Canals are sited on the higher ground, and the drains in the lower. The continued use of saline water for irrigation causes deposits of salts and soil deterioration so that crops cannot be grown. Sodium chloride and bicarbonate are the most harmful; water whose content is more than 700 parts per million of dissolved matter, consisting mainly of these salts, will do harm if used regularly for irrigation. Without drainage, lower concentrations will be harmful.

MAJOR IRRIGATION SYSTEMS

United States.—The western half of the United States, except for a strip along the coast averaging about 150 miles wide, has an annual rainfall of less than 20 inches. In the areas best suited for farming, the rainfall is insufficient in the growing season to produce good crops. Irrigation, which was early practiced by the Indians of the Southwest, has now developed until about 25 million acres are irrigated; more than three quarters of this development has been accomplished by private enterprise. About 170 million acres are cultivated by dry farming, but the greater part of suitable land is still uncultivated. The Bureau of Reclamation estimates from stream measurements that the available water is enough for the irrigation of another 17 million

acres. The principal irrigated crops are rice, sugar beets, vegetables, and fruits, which are almost entirely grown by irrigation; of the cotton, hay, and forage crops less than half are irrigated. Food grain crops are mostly grown by dry farming.

In drawing up projects for irrigation, it is advisable to combine it with other objectives, if possible, though the demands of irrigation, hydroelectric power, navigation, and domestic and industrial water are not entirely compatible. In the United States two large undertakings of this kind may be mentioned: the Colorado River and Columbia River projects. The principal work in the Colorado Basin is the Hoover Dam in Boulder Canyon, which serves several purposes. It provides a storage reservoir with a capacity of 32 million acre-feet (40 billion cubic meters), second in size only to the reservoir created in Lake Victoria by the construction of the Owen Falls Dam (200 billion cubic meters gross). It regulates the lower course of the river for irrigation and flood protection, provides domestic and industrial water for southern California, and produces large quantities of electric power, which is used in California, Arizona, and Nevada. The largest irrigation area dependent on the Colorado is in the Imperial and Coachella valleys, to which water is brought by the All-American Canal, taking off the river above the Imperial Dam. The total area irrigated in the two valleys is more than 500,000 acres.

The area known as the Columbia Basin Project contains more than 1 million acres of irrigable land, to be irrigated from the Grand Coulee Dam and subsidiary dams and works. The Grand Coulee, completed in 1942, was the largest masonry structure built up to that time, and attached to it is one of the world's largest power plants. Part of its power is assigned to pump water from Lake Franklin D. Roosevelt, formed by the dam, up to an equalizing reservoir in the Grand Coulee, which serves the canals. The pumping plant, when completed (by 1960, 6 of the ultimate 12 hydraulic pumps had been installed), will be able to pump 19,200 cubic feet (544 cubic meters) a second to a height of 280 feet. Working at full bore it would use one third of the power of the station. The pumps, however, are operated during the off-peak period and so do not interfere with commercial demands. These projects and many others have been carried out by the Bureau of Reclamation in the Department of the Interior. Repayments to the government for construction costs come primarily from water users on the irrigation projects and from the sale of power generated by hydroelectric plants operated in connection with some of the dams.

Nile River Basin.—The Nile, with its length of 4,160 miles and its varied basin, presents most of the problems involved in the utilization of water on the largest scale. The greater part of its water comes from rain falling on the mountains of Ethiopia from April to October. The result of this is that the river in Egypt and the Sudan rises to a peak in August and September and falls to a minimum in May. The average extreme 10-day mean volumes are about 730 and 45 million cubic meters (tons) per day on the main river where it enters Egypt.

Egypt is entirely dependent on irrigation (more than 6 million acres cultivated), the Sudan partly so (more than 1 million acres irrigated), and in the southern part of the basin where rain

crops are grown, the advantage of supplementary irrigation is beginning to be realized. So far the supply is insufficient for present cultivation from the beginning of February to the end of July, on the average, and is supplemented by storage from the floods. This storage is held behind the Sennar Dam on the Blue Nile, for the use of the Sudan; and by the reservoirs formed by the Jebel Aulia Dam on the White Nile, just above Khartoum, and the Aswan reservoir, for the use of Egypt. The low-stage supply supplemented by the stored water is distributed according to forecasts based on the fairly regular fall of the river after the flood and, when the river begins to rise, on the amount of water arriving in the southern Sudan. A short supply is met by reducing the allowance to the standing crops, limiting the rice area to suit the supply, and delaying the irrigation of fallow land until reports arrive from the upper reaches that a sufficient supply is on the way.

The limit of cultivation possible with these reservoirs has been reached and in years of very low flood cannot be completely supplied. It is therefore necessary to look to overyear storage so that the good years can help the bad. Such storage is possible in Lakes Victoria and Albert in central Africa and has been provided in Lake Victoria by the Owen Falls Dam at the exit of the Nile, which also provides power for Uganda. However, the storage is of little use to Egypt and the Sudan until dams are constructed to regulate Lakes Kioga and Albert, and the Jonglei Canal is completed to bypass the swamps of the Sudd region in the southern Sudan, and so reduce to a reasonable proportion the loss of 50 per cent of the water which takes place there. The construction of these projects would make it possible

to obtain nearly the maximum benefit from the White Nile by overyear storage.

The largest volume of unused water remaining after this lies in the excess flood waters of the Blue Nile and Atbara River, which at present escape to sea. This is a very variable quantity, since in the lowest year on record the total supply of the Nile would be insufficient for the needs of present cultivation, while in a high flood it would be double the requirements. To deal with these variations, overyear storage is required, preferably on the main Nile. For this purpose the High Aswan Dam project has been proposed by Egypt, to be used for annual working, for overyear storage, for flood protection, and for hydroelectric power. Other projects for annual storage for use in the Sudan are dams on the Blue Nile at Roseires, not far from the Sudan-Ethiopian frontier, and on the Atbara.

Many difficulties have to be overcome, apart from those of construction, before such a complicated system of projects can be made into a smoothly working machine. Operation will be based on the regular measurements, made for many years, of the flow of the principal tributaries at salient points all over the basin. The technical advisers of the Sudan government, collaborating with International Business Machines, have made an investigation by means of an electronic computer of the possible effects of various combinations of projects, old and new, on the regulation of the Nile, using the records of 50 years. No doubt, as further projects are constructed, electronic computers will be used to make the forecasts and to deduce from them the suitable regulation of the multiple projects.

Another complication is that the Nile is an international river flowing through seven countries, in all of which the population is increasing rapidly, and all have an interest in some degree in the regulation of the river. Since water requirements for all the potentially irrigable land in the basin are more than the supply of the whole river, even if used to the last drop, maximum benefits can be obtained from the river only by the close collaboration of all the basin countries.

Dams, Canals, and Other Works.—The world's most spectacular constructions for irrigation and other purposes are the great dams built of hewn stone, concrete, or earth. Particulars of some large dams are as follows.

Dam	Height (feet)	Length (feet)	Type	Purpose ¹
Grand Coulee, U.S.	550	4,173	Concrete	I, F, P, R
Shasta, U.S.	602	3,460	Concrete	I, F, P
Hoover, U.S.	726	1,244	Concrete	I, F, P, R
Fort Peck, U.S.	250 ²	21,026	Earth fill	F, P, N
Aswan, Egypt	140	7,000	Granite	I, P, N

¹ I, irrigation; F, flood control; P, power production; R, river regulation; N, navigation.

² Height above stream bed.

The Bhakra Dam on the Sutlej River in India, scheduled for completion in 1962, will have a height of 680 feet. Two high dams, higher than anything existing, had been proposed, but were later dropped. Of these the proposed Kosi River Dam in the Himalayas was replaced in 1953 by a barrage, diversion channel, and embankments. A very high proposed dam in a gorge of the Hwang Ho (Yellow River) in China was replaced in 1957 by a large multipurpose scheme for flood

Reservoirs of irrigation water for Egypt are controlled by the Jebel Aulia Dam near Khartoum in the Sudan.

George Rodger from Magnum

control, irrigation, power, and navigation. The scheme consists of 5 dams forming large storage reservoirs, 1 dam being nearly 400 feet high and another with a reservoir capacity of 60 billion cubic meters (50 million acre feet), as well as a number of regulating dams or barrages. The largest barrage in the world is the Sukkur Barrage on the Indus River in Pakistan, which is nearly a mile long and diverts water into 7 large canals with a discharging capacity of more than 40,000 cfs. (cubic feet per second). A barrage at Kotri lower down the Indus, of about the same size as the Sukkur Barrage, was completed in the 1950's, increasing the irrigated area in the lower river and in its delta. (See also DAMS.)

Other important irrigation works are canals. One of the largest is the Ibrahimiya Canal, which irrigates Middle Egypt; it has a length of 250 miles and a maximum discharge of 29,000 cfs., which irrigates 1¼ million acres. The All-American Canal in California has a maximum discharge of 13,000 cfs. and irrigates about half a million acres. The Godavari and Kistna canal systems in India each have total discharges of 14,000 cfs. and dependent areas of about 1 million acres. The proposed Sudd Diversion (Jonglei) Canal in the Sudan was projected to carry 22,000 cfs. but may ultimately carry more. The Grand Canal of China is the oldest and longest canal in the world. Begun in the 7th century and completed in the 13th and 14th centuries, it extends from Hangchow, south of the Yangtze River, to north of the Hwang Ho, where it connects with the Pei Ho on which is Tientsin. It was part of an extensive system of artificial channels, connecting several river systems, which enabled irrigation to be developed in the flat Yangtze River area.

Another type of work that is sometimes an adjunct to irrigation projects is the aqueduct, which also has a long history. Perhaps the largest is the Colorado River-Los Angeles Aqueduct (240 miles long), which delivers water to Los Angeles and 12 other Californian cities. (See also AQUEDUCTS.) Tunnels also play a part in transferring water from the watershed of one river to that of another. Of these the Alva B. Adams Tunnel (13 miles long) through the Rocky Mountains in Colorado may be mentioned, and also the projected tunnels of the Snowy Mountains Hydroelectric Scheme in Australia. See also TUNNELS AND TUNNELING—*Tunnel Classes and Their Characteristics* (Water Tunnels).

Projected Expansions.—Irrigated areas are expanding all over the world. Besides the United States with 25 million acres, India with 80 million acres (35 million from canals and the remainder from wells) has many projects under way. Communist China in 1957 announced a program that would more than double its irrigated area, increasing it to 150 million acres. The USSR has begun large schemes of expansion in south Russia from its rivers, and also east of the Caspian Sea. Iraq is likewise expanding its irrigated area. Besides the Nile projects, there are undertakings for development in North and West Africa and in South Africa, as well as in South America and Australia.

Scientific Consultant to the Ministry of Public Works, Egypt.

IRTYSH RIVER, ĭr-tish', river, USSR, in Central Asia and western Siberia. About 2,750 miles long, the Irtysh is the longest tributary of the Ob River, which it joins on the left side; it rises in the northern part of China's Sinkiang-Uigur Autonomous Region, where it is known as the Black Irtysh. Descending from the west slopes of the Mongolian Altai Mountains, the river flows west into Lake Zaisan in the Kazakh SSR. On leaving the lake, it assumes the name Irtysh and flows generally northwest past the Kazakh cities of Ust-Kamenogorsk, Semipalatinsk, and Pavlodar, and past Omsk and Tobolsk in Siberia to join the Ob River near Khanty-Mansk.

The Irtysh River receives several important tributaries, including the Bukhtarma, Om, and Tara rivers on the right, and the Ishim and Tobol rivers on the left. During the ice-free navigation season, which lasts from May to November, the river is used by shipping over virtually its entire course. The upper course of the Irtysh has a precipitous fall favorable for the construction of large hydroelectric stations. The 330,000-kilowatt Ust-Kamenogorsk station was opened in 1952, and the Bukhtarma station (435,000 kilowatts), situated 15 miles below the mouth of the Bukhtarma River, was opened in 1960. The Bukhtarma reservoir, when filled, will merge with Lake Zaisan and raise the lake level by 30 feet. The Irtysh power stations supply the mining and smelting industries of eastern Kazakhstan. The river is a potential source of water for the industrial area of central Kazakhstan, which is to be supplied by the planned Irtysh-Karaganda Canal.

THEODORE SHABAD,
Author of "Geography of the USSR."

IRÚN, ê-rōōn', town, Spain, in Guipúzcoa Province, on the left bank of the Bidassoa River (forming the frontier with France) near its effluence into the Bay of Biscay. A port of entry, it lies opposite Hendaye, France, across the river, spanned by an international bridge. The first Spanish railway stop on the Paris-Madrid route (Madrid is 396 miles distant by rail, 298 miles by road), Irún has a large customhouse and transit trade, and is a center of industry (rolling stock, cement, matches, electrical equipment, cider, liqueurs), agriculture (corn, chestnuts, apples, other fruit), and mining (iron, lead). It has an ancient church, rebuilt in 1508 and restored in 1912, and a 17th-century Renaissance-style town hall. Strongly defended by the Loyalists in the Civil War of 1936-1939, it fell to the Nationalists on Sept. 4, 1936. Pop. (1950) 19,452.

IRUS, i'rūs, nickname of Arnaeus, the huge beggar of Ithaca in Homer's *Odyssey*, who served Penelope's suitors as a messenger and was badly defeated by Odysseus in a fist fight. Irus became the prototype of other beggars in literature and was the name of the disguise-changing character in George Chapman's play, *The Blind Beggar of Alexandria* (1598).

IRVIN, William Adolph, American industrialist: b. Indiana, Pa., Dec. 7, 1873; d. New York, N. Y., Jan. 1, 1952. In 1894, Irvin began working for a sheet steel and tin plate manufacturer in Apollo, Pa., and after the firm was absorbed by the American Sheet and Tin Plate Company, he was placed in charge of plant operations in 1924. He moved to New York in 1931 to become vice president of the United States Steel Corporation, whose fourth president he became in 1932. After his retirement from the presidency on Dec. 31, 1937, he helped reorganize the National Safety Council, and from 1942 served as chairman of its board of trustees.

IRVINE, ū'r'vīn, Sir James Colquhoun, Scottish chemist: b. Glasgow, Scotland, May 9, 1877; d. St. Andrews, June 12, 1952. After completing studies at the Royal Technical College in Glasgow and at St. Andrews and Leipzig universities, he became professor of chemistry at St. Andrews, and, from 1921, university principal and vice chancellor. For his outstanding research on the structure of carbohydrates, he was awarded the Davy Medal of the Royal Society in 1925. He was knighted in the same year.

IRVINE, William, American Revolutionary War general: b. near Enniskillen, Ireland, Nov. 3, 1741; d. Philadelphia, Pa., July 29, 1804. After studying medicine with the celebrated physician, George Cleghorn, at the University of Dublin, he served as surgeon aboard a British ship of war during part of the Seven Years' War. In 1764 he emigrated to Carlisle, Pa., where he launched a medical practice.

At the beginning of the Revolutionary War he became a member of the provincial convention assembled in Philadelphia on July 15, 1774. Three years later he was appointed by Congress as commander of the 6th (later 7th) Pennsylvania Infantry Regiment. He was sent with his troops to Canada and in June 1776 was captured by the British during the engagement at Three Rivers. Released through an exchange of prisoners on May 6, 1778, he was promoted on May 12, 1779, to brigadier general in the Continental Army and was assigned to command the 2d Pennsylvania Brigade. In the autumn of 1781, he was ordered to Fort Pitt (Pittsburgh), where he retained command of the troops on the western frontier until October 1783.

Rewarded by Pennsylvania with a generous land grant, General Irvine in early 1785 was appointed state agent in charge of distributing lands to troops of the commonwealth. He recommended that Pennsylvania purchase from the federal government the tract known as the Erie Triangle, and the state's favorable reaction gave Pennsylvania its outlet on Lake Erie.

General Irvine was a member of Congress under the Articles of Confederation (1786-1788) and of the 3d Congress under the Constitution (1793-1795). He commanded the Pennsylvania troops which quelled the Whiskey Rebellion

(q.v.) in 1794, and in 1800 was appointed superintendent of military stores in Philadelphia.

Consult Butterfield, Consul W., ed., *Washington-Irvine Correspondence* (Madison, Wis., 1882); Boyd, Lucinda J., *The Irvines and Their Kin* (Louisville, Ky., 1898; rev. ed., 1908).

IRVINE, city, Kentucky, seat of Estill County, situated in a truck-farming area along the Kentucky River, 38 miles southeast of Lexington. Irvine's manufactures include railroad shops, sawmills, clothing mills, and some oil refining. Pop. 2,955.

IRVINE, burgh, Scotland, situated in north Ayr County about 31 miles southeast (by road) of Glasgow, for which it functioned as a port before the deepening of the Clyde. Irvine's harbor, formed by the confluence of the Irvine and Garnock rivers, was improved in the 1870's, and is used for the shipping of coal, although it is not deep enough for large modern vessels. Principal manufactures include chemicals, foundry products, hosiery, soap, and bottles.

Established as a royal burgh about 1230, Irvine includes among its places of historical interest an academy, whose foundations pre-date the Reformation, and the ruins of Norman castles. Robert Burns worked in Irvine as a flax dresser (1781-1783). Pop. (1951) 14,741.

IRVING, Edward, Scottish preacher and founder of the Catholic Apostolic Church: b. Annan, Scotland, Aug. 4, 1792; d. Glasgow, Dec. 7, 1834. Graduated from the University of Edinburgh in 1809, he taught school for eight years, meanwhile becoming a licensed preacher of the Church of Scotland in 1815. In October 1819, he became Dr. Thomas Chalmers' assistant in St. John's parish, Glasgow, until 1822.

In 1822, Irving became minister of the Caledonian Asylum chapel in Hatton Garden, London. Here the force and eloquence of his sermons, some of which were published in 1823 in *For the Oracles of God*, attracted large congregations. He began, however, to publish unorthodox theological views which were somewhat mystical and prophetic in character and which preached the imminence of Christ's second coming. His *Sermons, Lectures, and Occasional Discourses*, in which his theological divergences were first distinctly observed, was published in 1828, and his tract, *The Orthodox and Catholic Doctrine of Our Lord's Human Nature* (1830), evidencing radical views on the human nature of Christ, soon subjected him to charges of heresy.

In early 1832 his inferences, especially in connection with the so-called "unknown tongues," first heard in March 1830 from the Scottish girl, Mary Campbell, led his congregation, which in 1829 had erected a large church for him in Regent Square, to prefer charges against him. On April 26, 1832, he was removed from his London pulpit, and on March 13, 1833, he was condemned for heresy regarding the sinlessness of Christ by the presbytery of Annan, and deposed from the ministry. Irving retired to Scotland broken in spirit and ill with consumption. With Henry Drummond, a banker, he helped organize in 1832 a Christian community which eventually became the Catholic Apostolic Church (q.v.), whose members were popularly known as Irvingites.

Consult Oliphant, Margaret O. W., *The Life of Edward Irving*, 2 vols. (London 1862); Carlyle, Gavin, *The Collected Writings of Edward Irving*, 5 vols. (London

1864-66); and Drummond, Andrew L., *Edward Irving and His Circle* (London 1937).

IRVING, Sir Henry (original name JOHN HENRY BRODRIBB), English actor-manager: b. Keinton Mandeville, England, Feb. 6, 1836; d. Bradford, Oct. 13, 1905. Employed first as a clerk in London, he made his theatrical debut at the Lyceum Theatre, Sunderland, on Sept. 18, 1856, in the role of Gaston in Bulwer-Lytton's *Richelieu*. For nearly three years he then appeared with an Edinburgh stock company. He first acted in London at the Princess' Theatre on Sept. 24, 1859, and soon moved on to Manchester, where he appeared at the Theatre Royal from 1860 to 1865.

Returning to London in 1866 he created his first outstanding successes as Doricourt in *The Belle's Stratagem* at the St. James' Theatre and as Digby Grant in James Albery's *The Two Roses* (1870), which ran for 300 performances. In 1871 began his long association with the Lyceum Theatre, where he created his powerful impersonation of Mathias in Leopold Lewis' melodrama, *The Bells*, following which he played the title roles in William G. Wills' *Charles I* (1872) and *Eugene Aram* (1873), and in *Richelieu* (1873). In 1874-1875, during a 200-night run at the Lyceum, he sustained the role of Hamlet so successfully that he raised himself to top rank among English actors. He followed with a series of original, if not distinguished, performances as Macbeth (1875), Othello (1876), and Richard III (1877).

In 1878, in association with Ellen Terry (q.v.), with whom he had first appeared in *The Taming of the Shrew* in 1867, he leased the Lyceum, which remained under his management for 21 years. Here he created excellent productions of *Hamlet* (1878), *The Merchant of Venice* (1879-1880), in which he created a dignified and sympathetic Shylock, *Othello* (1881), *Romeo and Juliet* (1882), *Much Ado About Nothing* (1882-1883), and *Macbeth* (1888). Outstanding among his non-Shakespearean performances was his Mephistopheles in Wills' *Faust* (1885-1887), which ran for 16 months to become Irving's greatest financial success.

Henry Irving's appearances in the provinces were equally successful, as were his performances during eight American tours commencing in 1883-1884 and ending in 1903-1904. His Lyceum company, with Ellen Terry, made its debut in New York, with Irving appearing as Mathias in *The Bells*.

Among Irving's last great performances were the title roles in Tennyson's *Becket* (1893, frequently revived), J. Comyns Carr's *King Arthur* (1895), and several plays by Victorien Sardou which were translated by Irving's son, Laurence Irving (q.v.). The latter productions included *Robespierre* (1899), especially written for the English actor; and *Dante* (1903), which was performed at the Drury Lane Theatre.

Although critics were by no means in accord on the merits of his acting, which was somewhat romantic in style and occasionally suffered from excessive gestures and unfortunate mannerisms of voice, most agreed that Sir Henry excelled his contemporaries in his originality, versatility, and vitality, and in his seriousness of purpose. Added praise for his stage managership derived from his elaborate productions and the quality of his supporting casts.

Irving was knighted in 1895, the first actor to be so honored, and was buried in Westminster Abbey on Oct. 20, 1905.

Consult Archer, William A., *Henry Irving, Actor and Manager* (London 1883); Brereton, Austin, *Life of Henry Irving*, 2 vols. (London 1908); Stoker, Bram, *Personal Reminiscences of Henry Irving*, 2 vols. (London 1906); Terry, Ellen, *The Story of My Life* (London 1908); Irving, Laurence H. F., *Henry Irving, the Actor and His World* (London 1951).

IRVING, Henry Brodribb, English actor-manager: b. London, England, Aug. 5, 1870; d. there, Oct. 17, 1919. The elder son of Sir Henry Irving (q.v.), he was educated at Marlborough College and New College, Oxford. After appearing at the Garrick Theatre in Thomas Robertson's *School* in 1891, he was admitted to the bar in 1894, but within a short time gave up law for the stage. In 1894-1895 he played at the Comedy Theatre with J. Comyns Carr, and later in 1895 toured the provinces with Ben Greet's company. He subsequently appeared notably in the lead role of Barrie's *The Admirable Crichton* (1903) and as Hamlet (1905) at the Adelphi.

After 1900 he became one of London's most successful stage managers, as lessee of the Duke of York's Theatre (1902), of the Shaftesbury (1908), of the Queen's (1909-1911), and of the Savoy (from 1913). He toured the United States in 1906-1907, Australia in 1911-1912, and South Africa in 1912-1913.

Irving also wrote several studies in criminology, including *The Life of Judge Jeffreys* (1898), *Studies of French Criminals of the Nineteenth Century* (1901), and *A Book of Remarkable Criminals* (1918).

Consult Brereton, Austin, "*H.B.*" and Laurence Irving (London 1922).

IRVING, Isabel, American actress: b. Bridgeport, Conn., Feb. 28, 1871; d. Nantucket, Mass., Sept. 1, 1944. She made her New York debut as Gwendolyn Hawkins in *The Schoolmistress* in January 1887. From 1888 until 1894, she performed with Augustin Daly's Company, and in 1897 she became a leading lady to John Drew's company at the Lyceum Theatre, where she appeared in *The Liars* (1898), *The Tyranny of Tears* (1899), and other plays. She also acted leading parts in England, creating the role of Lady Jocelyn Leigh in *To Have and to Hold*.

Engaged by Clyde Fitch, she returned to the United States to appear in *The Toast of the Town* (1906) and *Susan in Search of a Husband* (1907). Throughout the next three decades she appeared in a wide variety of roles, including that of Mrs. Dallas-Barker in *Smith*, in which she co-starred with John Drew (1909-1911). Among her final performances were roles in *We Moderns* (1924), *Craig's Wife* (1926-1927), *Uncle Vanya* (1930), and *Three Wise Fools* (1936).

IRVING, John Duer, American geologist: b. Madison, Wis., Aug. 18, 1874; d. France, July 20, 1918. The son of Roland Duer Irving (q.v.), he was graduated from Columbia College in 1896 and later served the United States Geological Survey as assistant geologist (1900-1906) and geologist (1906-1907). From 1907 to 1918 he was professor of economic geography at the Sheffield Scientific School of Yale University. He was editor of the journal, *Economic Geology*, and the author of *Economic Resources of the Northern Black Hills* (1904).

IRVING, Laurence (Sydney Brodribb), English actor: b. London, England, Dec. 21, 1871; d. Canada, May 29, 1914. The younger son of Sir Henry Irving (q.v.), he received his formal education at Marlborough College and the Collège Rollin in Paris. Interested in the diplomatic service as a career, he studied for three years in Russia, but following his debut in a Shakespearian role at Dundee in 1893, he remained on the stage. He made his London debut in Barrie's *Walker, London* in 1894, and then starred in the provinces.

From 1900 to 1904, Laurence performed as a member of his father's company, and soon afterward created the role of Crawshay in *Raffles*. In 1908-1909 he visited the United States, where he acted in several of his own sketches, and in 1912 appeared back in London as Iago in the *Othello* of Sir Herbert Tree's company at His Majesty's Theatre. He lost his life aboard the *Empress of Ireland*, which sank in the St. Lawrence on May 29, 1914.

Irving wrote *Peter the Great* (1897; produced by his father in 1898) and *Richard Lovelace* (produced in New York in 1901), and also translated Maxim Gorky's *The Lower Depths* (1912) and several plays by Victorien Sardou in which his father appeared.

Consult Brereton, Austin, "H.B." and Laurence Irving (London 1922).

IRVING, Roland Duer, American geologist: b. New York, N. Y., April 29, 1847; d. Madison, Wis., May 27, 1888. The father of John Duer Irving (q.v.), he was a graduate of the Columbia School of Mines (1869). Professor of geology and mineralogy at the University of Wisconsin from 1870, he also served as assistant state geologist between 1873 and 1879. From the early 1880's he was geologist in charge of the Lake Superior division of the United States Geological Survey, for which he contributed valuable studies on copper and iron ores in the Superior region.

IRVING, Washington, American author: b. New York, N. Y., April 3, 1783; d. Tarrytown, Nov. 28, 1859. His father, William Irving, a merchant, went to New York from the Orkneys in 1763, having two years before married Sarah Sanders, daughter of Cornish parents. Washington was the youngest of the 11 Irving children, who included William, a poet and politician, and Peter, also a writer. His formal schooling was far from thorough, but he was an enthusiastic reader of English authors.

At the age of 16, Washington entered a law office, and in 1802 began authorship by contributing humorous sketches on social and theatrical life in New York above the signature of Jonathan Oldstyle to *The Morning Chronicle*, a daily edited by his brother Peter. These were independently published in 1802-1803 as *The Letters of Jonathan Oldstyle, Gent.*

Developing symptoms of consumption, he sailed in 1804 for France and spent two health-restoring years in travel on the continent and in England. On his return to the United States he was admitted to the bar, but instead of practicing law he again turned to writing. In 1807, with his brother William and with James K. Paulding, he began issuing a series of charming and witty essays published as *Salmagundi; or, the Whim-Whams and Opinions of Launcelot Langstaff, Esq., and Others* (1807-1808), the success of which settled him on his future career.

At the close of the following year he set about reshaping his burlesque history of New York, which he had begun earlier with Peter Irving on a different plan. In the midst of this work he lost by death in 1809 his fiancé, Matilda Hoffman, daughter of a prominent New York lawyer, in whose office Irving had finished his legal studies. The completion of the book, Diedrich Knickerbocker's *A History of New York from the Beginning of the World to the End of the Dutch Dynasty* (1809), was the only solace that he permitted himself in the first months of grief. This first outstanding American comic chronicle proved to be a brilliant satire on history, politics and government, and manners.

In 1810, Irving was received into partnership by his brothers Peter and Ebenezer, who were founding an importing house. His brothers wished to provide him with the means, without expenditure of his time on business, to continue his chosen career. In 1813-1815, Washington edited or contributed to the *Analectic Magazine*, published in Philadelphia. After the burning of Washington, D.C., by the British in 1814, he offered his services to New York and was made aide-de-camp to Governor Daniel Tompkins, with the rank of colonel. At the close of the war, Irving went to England, where he was received with distinction by the American artists Washington Allston and Charles R. Leslie, and by Sir Walter Scott, Thomas Campbell, Thomas Moore, and other literary men.

In 1818 the firm of Peter and Ebenezer Irving failed, and Washington's pleasant rambles in England and Scotland came to an end, and he set himself to work in London with his writing. Early in the next year he sent over for publication in New York and Philadelphia the first number of *The Sketch Book of Geoffrey Crayon, Gent.*, which, with others that followed, eventually contained *The Voyage, The Wife, Rip Van Winkle, The Legend of Sleepy Hollow*, and other sketches. Successfully received, *The Sketch Book* was brought out in a London edition by John Murray in 1820, and its popularity was such that Murray soon also published *Bracebridge Hall; or, The Humorists* (1822) and *Tales of a Traveller* (1824).

In 1826, Irving went to Madrid at the urging of his friend, Alexander H. Everett, American minister to Spain, who advised Irving to translate the *Colección de los Viajes y Descubrimientos* (of Columbus), by Martín Fernández de Navarrete, then being issued in parts. The American author found the work impracticable to translate because it was a collection of sources rather than a consistent narrative. Instead, he prepared *A History of the Life and Voyages of Christopher Columbus*, finished in 1828. This first serious product of Irving's creative skill succeeded in retaining much of the ease and charm of *The Sketch Book* and of *Tales of a Traveller*, and considerably enhanced his reputation. Further fruits of Irving's Spanish studies and travel were *A Chronicle of the Conquest of Granada* (1829), *Voyages and Discoveries of the Companions of Columbus* (1831), and *The Alhambra* (1832). In the meantime, Irving had been made secretary of the American legation in London in 1829, and received the medal of the Royal Society of Literature (1830) and an I.L.D. degree (1831) from Oxford.

In 1832 he returned to the United States and accompanied an Indian commission to Fort Gibson on the Arkansas River. From his experiences he wrote *A Tour on the Prairies* (1832), published as

the first volume of *The Crayon Miscellany* in 1835. The second volume, *Abbotsford and Newstead Abbey*, and the third, *Legends of the Conquest of Spain*, followed in a few months. He now bought the little van Tassel farm at Tarrytown, N.Y., and began to enlarge its Dutch cottage and improve the grounds. To this home, called "Sunnyside," he and the brothers who had aided him in earlier years soon moved from New York City. In 1836 he finished *Astoria*, with the help of his nephew, Pierre M. Irving, from materials furnished by John Jacob Astor. The next year he published *The Adventures of Captain Bonneville, U.S.A.*, properly a continuation of the preceding. He then began a history of the conquest of Mexico, but on learning that William H. Prescott was at work on the same subject, resigned the task to him. In 1839 he was engaged to write for the *Knickerbocker Magazine*, and furnished monthly articles for about two years. In 1842 he was appointed minister to Spain, and for the next four years wrote little. On his return he arranged with George P. Putnam for a complete edition of his works, in 15 volumes, to which he added *Oliver Goldsmith* (1849) and *Mahomet and His Successors* (1850). The way was now open for the *Life of Washington*, which had long been contemplated. In 1855 appeared *Wolfert's Roost*, mainly a compilation of his early notebooks, and two volumes of the *Life*. The work told on his strength, and the fifth and last volume, finished in March 1859, left him a broken man. His death was from heart disease.

Irving's most salient characteristics as a writer are his romantic affection for the relics and legends of the past and his ability to transmit this feeling to his readers. Bound up with this sensibility is his loving craftsmanship in words, which made him the first "classic" in the literature of the United States. His fatal limitation is a blindness to the spirit of his own time, a failing which kept him a minor writer despite the high order of his artistic skills. The standard edition of his *Works* was published in 21 volumes (1860-61; reprinted in 12 vols., 1881). See also KNICKERBOCKER HISTORY OF NEW YORK, THE; LEGEND OF SLEEPY HOLLOW, THE; SKETCH BOOK, THE.

Consult Irving, Pierre M., *The Life and Letters of Washington Irving* . . . 4 vols. (New York 1862-64); Williams, Stanley T., *The Life of Washington Irving*, 2 vols. (New York 1935).

IRVINGTON, ū'r-vīng-tūn, town, New Jersey, in Essex County, at an altitude of 212 feet, adjoining Newark on the southwest. It is a residential suburb served by the Lehigh Valley Railroad with an industrial section where such varied products as chemicals, insulating material, toy trains, hosiery, cutlery, and metal castings and tools are made. Settled in 1692, it was called Camptown until 1852, when it was renamed in honor of Washington Irving. It was incorporated as a town in 1898, and has commission government. Pop. 59,379.

IRVINGTON, village, New York, in Westchester County, at an altitude of 175 feet. Located on the Hudson River and served by the New York Central Railroad, it is 22 miles north of New York City and immediately south of Tarrytown. A settlement made on the site about 1650 was called Dearman until 1854, when it was renamed for Washington Irving, who had bought

10 acres here called Wolfert's Roost, which he renamed Sunnyside. In the 1880's many rich men lived here: Jay Gould, Cyrus W. Field, the Morgans, Fargos, and Harpers. The Jonathan Odell House (1693) was a Revolutionary War inn. The Children's Museum and Irvington House for Cardiac Children are also located here. Although Irvington is mainly residential, it has several large industries, notably the manufacture of greenhouses and ventilating boilers. The village was incorporated in 1872. Pop. 5,494.

IRWIN, ū'r-wīn, May (real name ADA CAMPBELL), American actress: b. Whitby, Ontario, Canada, June 27, 1862; d. New York, N.Y., Oct. 22, 1938. She made her debut at the Adelphi Theater, Buffalo, N.Y., in 1875, and in 1877 went to New York City, joining Tony Pastor's company, where Augustin Daly discovered her in 1883. For the next four years she was a member of Daly's company, making her mark as a comedienne. She excelled in farce and starred in many successes, from *The Widow Jones* (1895) to *No. 13 Washington Square* (1915), which was performed in Washington for President Woodrow Wilson and his cabinet. She also popularized many hit songs of the day including *After the Ball*, which she sang in *The Poet and the Puppets* (1893), and *A Hot Time in the Old Town in Courted into Court* (1896). She was one of the first to introduce the style of singing known as ragtime. She retired in 1922.

IRWIN, Wallace (Admah), American humorist and novelist: b. Oneida, N.Y., March 15, 1875; d. Southern Pines, N.C., Feb. 14, 1959. Brother of Will Irwin (q.v.), he was brought up in Colorado, attended Stanford University, and in 1900 became a special writer on the San Francisco *Examiner*. In 1904 he moved to New York City, where he wrote for the *Globe* and other publications, working as a free lance writer from 1907. Irwin published more than 20 novels and books of humor and verse, of which the best-known are probably his Japanese dialect stories, notably the *Letters of a Japanese Schoolboy*, begun in *Collier's Weekly* in 1906 and first published in book form in 1909. His novels include *Seed of the Sun* (1921), about the Japanese in California, the result of an assignment for the *Saturday Evening Post* in 1919; *Lew Tyler and the Ladies* (1928); and *Young Wife* (1936). He also assisted Dr. Sylvester M. Lambert of the Rockefeller Foundation in writing *A Yankee Doctor in Paradise* (1941).

IRWIN, Will (in full WILLIAM HENRY IRWIN), American journalist and author: b. Oneida, N.Y., Sept. 14, 1873; d. New York, N.Y., Feb. 24, 1948. Brother of Wallace Irwin (q.v.), he graduated from Stanford University in 1899, entered journalism in San Francisco, and in 1904 went to New York City as a reporter on the *Sun*, for which he wrote his journalistic classic—the story of the earthquake and fire which partly destroyed San Francisco (1906)—published in book form as *The City That Was* (1907). From 1908 he devoted himself to general magazine writing except for the years 1914-1918, when he was a war correspondent for various American publications and the London *Daily Mail*. He also wrote novels and plays, but is best remembered for his reportage. His published works include a volume *The Hamadryads*

(verse, 1904); *Old Chinatown* (1908); *The Confessions of a Con Man* (1909); *The House of Mystery* (1910); *The Red Button* (1912); *Where the Heart Is* (1912); *Men, Women and War* (1915); *The Latin at War* (1916); *A Reporter in Armageddon* (1918); *The Thirteenth Chair*, play, with Bayard Veiler (1916); *The Next War* (1921); *Columbine Time* (1921); *Christ or Mars* (1923); *Youth Rides West* (1925); *How Red is America?* (1927); *Highlights of Manhattan* (1927); *Herbert Hoover—A Reminiscent Biography* (1929); *The House That Shadows Built* (1929); *Lute Song*, play with Sidney Howard (1930); *Propaganda and the News* (1936); *Spy and Counterspy*, with E. V. Voska (1940); *The Making of a Reporter* (1942); *Spies and Saboteurs*, with T. M. Johnson (1943).

ISAAC, ʾīzāk; ʾīzīk, Hebrew patriarch, son of Abraham and Sarah, the name signifying "laughter." According to the Biblical account given in Genesis 17, the birth of Isaac when Abraham was 100 years old and Sarah 90, was the guaranty of the existence of a covenant, in virtue of which, the descendants of Abraham would be a "chosen people" receiving special enlightenment. His life is highlighted in Scripture chiefly through the incidents of the dismissal of Hagar's son, whom Sarah had seen mocking Isaac (Genesis 21); the offering of Isaac as a sacrifice (Genesis 22) which was providentially averted, being only a test of faith and obedience; his marriage to Rebekah, the Aramean in his 40th year (Genesis 24); the birth of the twins Esau and Jacob after 20 years (Genesis 25), their later strife; Isaac's dream and God's promise to him of future enlargement (Genesis 26). The story of his old age is contained in the narration of the growing, open enmity between his two sons which had been foretold before their birth. In anticipation of his own death, Isaac bade Esau bring him some venison to receive his blessing; Jacob urged by Rebekah who had heard Isaac's request, appeared as Esau before the blind father to receive the blessing promised to his brother; and how Esau learned of Jacob's action and Jacob fled from Esau's wrath—are episodes that preserve after thousands of years their dramatic interest, while for the pulpit of all creeds they retain their power. All of the incidents of Isaac's life have become of great importance in metaphorical usage both in sacred and secular literature. At the age of 180 Isaac died at Hebron, cheered by the return of Jacob and his family from Mesopotamia, and was buried by both of his sons in the cave of Machpelah beside Abraham and Sarah (Genesis 35).

The early rabbis in the Midrash make frequent reference to Isaac. His name is made a compound of two Hebrew words denoting "Law was issued." In the Hebrew letters of his name allusion is found to the ten words (declogue), and the respective ages of Sarah and Abraham at his birth. To silence evil tongues on the occasion of Isaac's weaning, Abraham's features were imprinted on his face, so that the likeness between father and son was very great. The sacrifice of Isaac furnishes a fertile field for Midrashic reflection and becomes a special feature of the Jewish liturgy. Christian interpretations sometimes regard it as a prefiguring of the crucifixion. Isaac is stated to have instituted the traditional afternoon prayer and to have had ex-

traordinary attributes. In Mohammedan legend, Ishmael appears substituted for Isaac as offering and other points of similarity with the rabbinical Midrash are to be observed.

ISAAC I COMNENUS, Byzantine emperor: d. 1061. He was the son of Manuel Comnenus (q.v.) an eminent general under Basil II, emperor of Constantinople, and was the first of his family to assume the purple. He had distinguished himself as a soldier and commander in the wars against the Arabs, in Asia Minor and had married a captive Bulgarian princess. In 1057 he succeeded to the throne upon the deposition of the aged and incompetent Michael VI. During his short reign he made many reforms which are credited with prolonging the empire. His financial measures, though they improved conditions, were extremely unpopular. He also strengthened the empire by successfully repelling the Hungarians and Petchenegs who had been threatening the northern borders (1059). He abdicated in 1059 on account of sickness, appointing a relative, Constantine Ducas, as his successor. He spent the remainder of his life in the monastery at Studion where he had received his education as a youth. His interests were not purely military or political; he left a manuscript, still in existence, on Homer, entitled *Scholion*. He also wrote two other works on the same subject *Characteristics* and *On the Works of Homer*.

Consult Gibbon, E., *History of the Decline and Fall of the Roman Empire*, vol. 5 (London 1898); Finlay, G., *History of the Byzantine and Greek Empires, 1057-1453* (Edinburgh 1854); id., *History of Greece*, vols. 2, 3, 4 (Oxford 1877).

ISAAC II ANGELUS, Byzantine emperor: d. 1204. He became sovereign of the East as successor of Andronicus I in 1185, by a revolution, and reigned 10 years. During his rule the empire suffered several unsuccessful military campaigns and the excessive taxes caused the revolt of the Bulgarians and Vlachs (1186). After promising free passage through his empire to the crusaders under Frederic I Barbarossa (q.v.) of Germany, he treacherously formed an alliance against them with Saladin (q.v.) but was compelled to keep his promises through force of arms. Isaac was a vicious and weak prince. He was dethroned, blinded, and imprisoned by his brother Alexius in 1195. Eight years later he was restored to the throne, reigned for six months (1203-1204), was again dethroned and soon after died in prison.

Consult Gibbon, E., *History of the Decline and Fall of the Roman Empire*, vol. 5 (London 1898); Finlay, G., *History of the Byzantine and Greek Empires, 1057-1453* (Edinburgh 1854); id., *History of Greece*, vols. 3, 4 (Oxford 1877).

ISAAC, ē'zā-āk; ē'zāk, Heinrich, Flemish composer: b. probably in Brabant or East Flanders about 1450; d. Florence, Italy, 1517. Summoned to Florence by Lorenzo de' Medici about 1480, he succeeded Antonio Squarcialupi as court organist, and set many of Lorenzo's carnival songs to music. In 1496, after the fall of the Medici, he entered the service of Emperor Maximilian. One of the great musicians of his day, he composed both secular and sacred works.

ISAAC OF ANTIOCH, ʾīzāk, Syrian churchman: b. probably at Edessa, early in the 5th century. He removed to Antioch about 450 A.D. and for very many years was abbot of a monastery near that city. Many of his works are lost, but about 190 extant metrical

homilies are attributed to him. Of these, some are certainly the work of another Isaac. See also SYRIAC LANGUAGE AND LITERATURE—*Literature*.

ISAACS, ê-sâks'; ê-sâ'âks, **Jorge**, Colombian novelist: b. Cali, Colombia, April 1, 1837; d. Ibagué, April 17, 1895. He was the son of a British Jew from Jamaica who married the daughter of an officer in the Spanish Navy. Isaacs first went to school in his native town, and at 11 was sent to Bogotá, where for five years he studied at various schools. These early years of his life are faithfully recaptured in the opening section of his sentimental *Maria* (published in 1867), one of the most widely read novels in Spanish America. Instead of going abroad to study medicine, however, as he wished to do—and as the hero of his novel does—he joined the army and became something of a hero himself. In 1856 he married, and soon after was engulfed in the seething political and military life of his country. The death of his father in 1870 forced him to face new and exacting responsibilities, and the failure of his father's business left him with his poetry and *Maria* as his only assets; however, the numerous editions of his novel never brought him much return in royalties. When the first edition of *Maria* was published, the distinguished Mexican author Ignacio Manuel Altamirano hailed it as superior to anything by René de Chateaubriand, a recognized leader in the French romantic movement; it was serialized in the *Monitor Republicano* in Mexico; and later in Argentina in the *Revista de Argentina*.

Appointed consul to Chile in 1872, Isaacs contributed articles and poems to Argentine, Chilean, and other publications throughout Latin America. Despite his growing renown, however, he felt homesick, and in November 1872 he returned to Colombia where, with a Chilean friend, he bought the hacienda Guayabonero in the Cauca Valley and for two years devoted himself unsuccessfully to agriculture. The last two decades of his life found Isaacs again active in war and politics, but without adding any peace, wealth, or sweetness to his bitter chain of disappointment and poverty.

In *Maria*, Isaacs' approach is basically romantic. His major theme is the deep and pure love of two young people (Efraín and María), which is blocked by the menace of an incurable disease (the epilepsy to which María is subject), and the opposition of Efraín's kind but severe father, who is also María's foster father. Such romantic embellishments as African interludes and sinister ravens lend touches of Mme. de Staël and Edgar Allan Poe to the style and suffuse the "noble savage" passages (idealizing the Negro and condemning slavery) with a honeyed sweetness and remoteness from reality reminiscent of Chateaubriand's *Atala*.

But this is only one side of Isaacs. He also excelled as a *costumbrista* or genre writer, skilled in sketching the scenes in which many of the events of his story occurred. If the love story of his novel is feeble and static, this is compensated for by the vividness of many secondary elements; among them are convincing descriptions of nature, and minor characters filled with the wisdom and humor of simple countryfolk, many of whom make fleeting but unforgettable appearances in the narrative. For example, modern readers will find more life, more flesh and

blood reality, in Salomé, a minor character occupying a few pages, than in the heroine, who, by contrast, seems pallid and unsubstantial.

ISABEAU, ê-zä-bô', or **ISABELLA** or **ELIZABETH OF BAVARIA**, queen of France: b. 1370; d. Sept. 24, 1435. She was the daughter of Stephen II, duke of Bavaria. In 1385 she was married to Charles VI, king of France, and was crowned with him on Aug. 24, 1389. When the king became subject to attacks of insanity (1392-1422), she acted as regent. Frivolous and vacillating, she became involved in scandalous intrigues, and worked solely to advance her own interests, sometimes siding with the Armagnacs and sometimes with the Burgundians. She was held prisoner by the Armagnacs in 1417, first at Blois, then at Tours. When liberated by John the Fearless, duke of Burgundy, she went completely over to the side of the Burgundians and the English. She was held mainly responsible for the Treaty of Troyes (1420), by which France was surrendered to the English and the right of her son to the crown of France was set aside in favor of Henry V of England, who married her daughter, Catherine of Valois. Her daughter Isabella of France married Richard II of England. Hated by the French for her part in the Treaty of Troyes, Isabeau lived at Paris, lonely and impoverished, until her death, when her son, who, with the help of Joan of Arc, had become Charles VII of France, had her body privately interred in the abbey at St. Denis.

ISABELA, ê-sä-vä'lä, province, Republic of the Philippines, in northeastern Luzon Island. It is the second largest province with a land area of 4,069 square miles. The Sierra Madre Mountains parallel its coast, which borders the Philippine Sea on the east. The Cagayan River flows north through the central part of the province. An important tobacco-growing region, it also raises rice, sugarcane, cacao, coffee, and corn. Two north-south highway arteries link Isabela with Cagayan Province on the north and Nueva Vizcaya Province on the south. There is daily air service to Manila and to Cauayan on Negros Island. Since 1950, about 50,000 acres in new reservations have been opened for land distribution, and an irrigation project is under way to reclaim an additional 58,000 acres. The province has a population (1948) of 264,495. The capital is Ilagan, pop. (1948) 35,384. Aparri, in Cagayan Province, is Isabela's port of entry.

ISABELA, municipality, Republic of the Philippines, in central Negros Occidental Province on Negros Island. It is in an area raising rice and sugarcane, and its chief industry is sugar milling. Binalbagan is nine miles to the west. Pop. (1948) 33,743.

ISABELLA I, ĭz-ă-bĕl'ă (called ISABELLA THE CATHOLIC; Span. ISABEL LA CATÓLICA), queen of Castile; b. Madrigal, Old Castile, April 22, 1451; d. Medina del Campo, Nov. 26, 1504. She was the daughter of John II of Castile and his second wife, Isabella of Portugal. She was married to Ferdinand II of Aragon in 1469. Upon the death of her brother, Henry IV of Castile, whose daughter Juana la Beltraneja was adjudged illegitimate, she herself became queen of Castile in 1474, and the two kingdoms of Aragon and Castile were brought together although they continued to be governed separately; both sovereigns were present at the transaction of state affairs for both kingdoms, and public ordinances of both kingdoms were signed by both Ferdinand and Isabella. Pope Innocent VIII conferred on the rulers the title of "Most Catholic," and Pope Alexander confirmed the title. Under their rule numerous reforms were made in political and ecclesiastical affairs, schools were established, and learning and the arts were developed. The Moorish kingdom of Granada was conquered in 1492, and the same year, under the special patronage of Isabella, Christopher Columbus made his first voyage to America, opening the way for Spain's colonial power in the New World. Less commendable was the establishment of the Inquisition (see INQUISITION—*The Inquisition in Spain*) as an instrument of political control. Isabella had great intelligence and a broad political vision, and her high moral character and sincere piety exerted a strong elevating influence on the Spanish court. In her reforms she was aided by her confessor, Francisco Jiménez de Cisneros. See also FERDINAND V, King of Castile; SPAIN—15. *History: 5th Century A.D. to 1492* (Development of the Christian States: Unification of Spain).

ISABELLA II (in full MARIA ISABELLA LOUISA), queen of Spain: b. Madrid, Spain, Oct. 10, 1830; d. Paris, France, April 9, 1904. She was the elder daughter of Ferdinand VII and his fourth wife, Maria Christina of Naples, and was declared heir to the throne in June 1833. She succeeded her father the following September, the Salic law having been set aside in 1830. Her mother acted as regent until 1840. The early years of the reign were disturbed by the First Carlist War (1833–1840), led by Isabella's uncle Don Carlos, who under the Salic law would have succeeded to the throne. In 1841, Gen. Baldomero Espartero became regent, but was overthrown by the Carlists in 1843, and Isabella was declared of age. In 1846 she married her cousin Francisco de Asís. Her reign was marked by continual party strife and frequent cabinet changes, and finally culminated in 1868 in an insurrection which forced her from the throne. In June 1870 she abdicated in favor of her son Alfonso XII. See also SPAIN—16. *History: 1492–1931* (Reign of Isabella II).

ISABELLA, the heroine of William Shakespeare's play *Measure for Measure* (q.v.), one of Shakespeare's noblest characters. She is a

novice in Vienna whose brother Claudio, under the strict laws of the city, has been condemned to death for seduction. Isabella pleads for his life with the self-righteous Angelo, who is acting as governor in the duke's absence, and he offers to spare Claudio in return for her honor. The duke, who has remained in Vienna in disguise to check upon Angelo's actions, arranges for her to pretend to accede, her place being taken by Mariana, Angelo's slighted fiancée. In spite of Isabella's supposed compliance, Angelo treacherously arranges to have Claudio executed, whereupon the duke confronts him. Angelo is spared from punishment upon Isabella's intercession and marries Mariana, and the duke declares his love for Isabella.

ISABELLA, (in full ISABELLA, OR THE POT OF BASIL), a narrative poem in ottava rima stanzas, written by John Keats and telling the story of the fourth novel of the fifth day in Giovanni Boccaccio's *Decameron*. It is the only completed part of a projected series of tales from the *Decameron* to be written by Keats and his friend John Hamilton Reynolds. It was begun in February 1818 and completed in April, and represents the chief transition in Keats' work between the *Endymion* of 1817 and the great poems that began in the autumn of 1818.

Isabella is a maiden of Florence who loves Lorenzo, a poor servant of her two cruel and proud brothers. These brothers, learning of her love, kidnap and murder Lorenzo and bury his body in a forest. Lorenzo's ghost appears to Isabella, who digs up the body, cuts off the head, and buries it in a flowerpot with a basil plant growing in it. The pot is stolen by her brothers, and Isabella dies of grief and madness.

Though not fully mature Keats, the poem has always been a favorite with Keats' readers. Charles Lamb asserted that there was nothing "more nakedly grand and moving in sentiment, in Dante, in Chaucer, in Spenser" than the scene of the digging up of the body; Leigh Hunt pointed out the felicity of the phrase "the two brothers and their murder'd man" (that is, the man they were planning to murder); Bernard Shaw, among others, called attention to the powerful tone of social protest in the characterization of the haughty brothers. Keats himself took a more detached view of the poem, saying in a letter to Richard Woodhouse (Sept. 21, 1819) that he would not publish it because "there is too much inexperience of life and simplicity of knowledge in it." But it was finally published in *Lamia, Isabella, The Eve of St. Agnes, and Other Poems* (1820).

NORTHROP FRYE,

ISABEY, ĕ-ză-bă', Jean Baptiste, French portrait and miniature painter: b. Nancy, France, April 11, 1767; d. Paris, April 18, 1855. He began his art training in Nancy, and in 1785 went to Paris, where he studied with Jacques Louis David and soon became famous as a portrait painter and miniaturist. His portraits of Napoleon are considered especially fine. The Louvre has many examples of his works in oil, crayon, water color, and on porcelain. Among them are

the 32 drawings of the *Coronation of Napoleon* (1804); *Stairway of the Louvre* (1817), a water color on ivory, considered a masterpiece; and the famous *La table des maréchaux*, painted on Sèvres porcelain, showing Napoleon I and his generals.

His son and pupil, EUGÈNE LOUIS GABRIEL ISABEY (1804–1886), became a marine and genre painter. Several of his paintings are in American museums, among them *The Banquet Hall* (The Metropolitan Museum of Art, New York City); *View of a Port* (Boston Museum of Fine Arts); *Sea Storm* (Chicago Art Museum); *Church Interior* (Baltimore).

ISAEUS, i-sē'ūs, Athenian orator: b. Chalcis, Euboea, about 420 B.C.; d. about 350 B.C. Little about his life is known, except that he was a pupil of Isocrates and a teacher of Demosthenes. Ranked among the so-called Ten Attic Orators, Isaeus owes his fame not to the delivery of his own orations, but to the composition of speeches for his clients to use in pleading their cases in law courts. By this work and by training aspiring orators he seems to have earned his living. Of 64 orations attributed to Isaeus—although even in antiquity only 50 were considered authentic addresses—there survive 11 on contested inheritances, 1 on civic rights, 44 titles of other speeches, 32 fragments of these, and 9 unidentified fragments. Apart from the addresses on the Attic law of succession to estates, in which subject Isaeus is our acknowledged authority, his other orations covered a variety of legal cases concerned with such matters as real property, adoption, guardianship, sureties, assault and battery, and municipal rights. Isaeus' renown for his cleverness in making the worse cause appear the better case is probably the strongest testimony payable to his skill in presentation of such intricate controversies as disputes over dispositions of inheritances often involve. His diction is so simple, his style so lucid, and his exposition so efficient, that the most complicated case becomes quite clear to the modern reader. The best Greek edition with English translation of his speeches is by Edward S. Forster, *Isaeus* (London and New York 1927).

ISAIAH, i-zā'yā; i-zī'ā, Hebrew prophet of the 8th century B.C. The Hebrew name of the great prophet, Y'sha'yahu or Y'sha'ya, is derived from two words meaning "salvation of Yahweh." In the history of prophecy, Isaiah belongs with Amos of Tekoa and Hosea ben Beeri, both of whom carried on their prophetic activity in the northern kingdom of Israel, and Micah of Moresheth, his southern contemporary. Isaiah was the son of Amoz, of whom nothing is known, and was a married man. His wife is called a prophetess (Isaiah 8:3), but this must not be taken to mean that she followed a prophetic calling. Two sons were born to him, both of whom bore names symbolizing the imminence of divine judgment upon Israel: Sh"ar-yashub (Shear-yashub), "(only) a remnant shall return," and Maher-shalal-hash-baz, "hastening to spoil, speeding to prey." For more than 40 years he was active as Yahweh's prophet in the southern kingdom of Judah. It is possible that he belonged to the aristocratic class; his style and manner seem to be those of an educated person. More

than any other prophet, his work is associated with the city of Jerusalem and the royal court. According to a late apocryphal tradition he suffered a martyr's death by being sawed asunder (consult the pseudepigraphic *Ascension of Isaiah*; compare the Ethiopic version with Hebrews 11:37).

Isaiah prophesied during the reigns of Jotham (742–735 B.C.), Ahaz (735–715 B.C.), and Hezekiah (715–687 B.C.). It was a period of great international conflict in which the military power of Assyria played a central role. The prophet's oracles are in general to be understood against the background of the successive crises evoked by Assyria's invasions of the Mediterranean littoral. His call came to him in the year 742 B.C., when Tiglath-pileser III or Pul (r. c. 745–727 B.C.) threatened Israel and exacted a heavy tribute from Menahem (II Kings 15:19). In his vision Isaiah sees Yahweh seated on His throne in the heavenly assembly, receives his commission to prophesy to "this people" (meant contemptuously), and then hears the terrible words of judgment (Isaiah 6:9–12). During the Syro-Ephraimitic war (734–733 B.C.) he warns Ahaz against entangling alliances and an appeal to Assyria (chaps. 7; 8; 17:1–11). Some of his most stirring oracles were delivered on the eve of Samaria's destruction in 722 B.C. (chaps. 9: 8–10:4; 5:25–30; 28:1–4). At the time when Sargon II (r. 721–705 B.C.) laid siege to Ashdod, Isaiah went through the streets of Jerusalem for three years naked and barefoot in order to symbolize the imminent fall of Egypt. Many oracles are preserved from the period of the invasion of Sennacherib about 705 B.C. (chaps. 10:5 ff.; 14: 24–32; 17:12–18:6; 22; 28:7–29; 30:1–17 and 27–33). The Messianic oracles are among the most notable and influential of all the prophet's utterances (chaps. 9:1–7; 11:1–9; 32:1–8). They are a vivid reflection of the royal theology associated with the house of David. It is significant that Isaiah has nothing to say about the Exodus, and next to nothing about the covenant.

Isaiah speaks with a vigor and eloquence matched by no other Old Testament prophet. His language is rich in imagery; his style chaste and stately. The variety of his allusions and his rhetorical devices reveal a mind of great versatility. The diversity of situation and intent finds expression in many literary forms and types. He uses the refrain effectively, as in the poem on the day of Yahweh (chap. 2:6–19) or that on the fall of Samaria (chaps. 9:8–10:4; and 5: 25–30). Like his compatriots he has a remarkable feeling for assonance, as his alliterations, paronomasias, and repetitions illustrate. His parable of the vineyard (chap. 5:1–7) is a superb example of his literary powers; its construction is firm, its repetition moving, its transition powerful, its climax shattering. His language is always consistent with the message he seeks to convey. Nowhere do we have a sense of labored speech; rather, his words flow forth in a way that seems inevitable.

The two pillars of the prophet's theology are Yahweh's kingship and holiness. As king, God is exalted over all the earth; He rules in majesty and power, though sometimes hidden (chap. 8:17). The final determinative force in history is His activity and sovereignty over events. His word goes forth, and events follow one another until His work is accomplished (chap. 9:8 ff.). Like his later successor, Second Isaiah

(chaps. 40-55), Isaiah is aware of the domination of the divine purpose in history (chaps. 14:24-27; 28:23 ff.). Assyria is the rod of God's anger, but in her vaunting and pride Yahweh of hosts will bring her down. Yahweh is the Holy One of Israel, and His holiness manifests itself not only as luminous power but in justice and righteousness. He has His day, and in the day of His appearing He will bring down all the temporal forces and powers which exalt themselves: *Yahweh alone will be exalted in that day*. Isaiah can be as trenchant in his condemnation of social evils as is Amos. Nor does he spare the worship of the people (chap. 1:10-17), but exposes the insincerity and corruption with which they say their prayers, offer their sacrifices, or celebrate their festivals. Yet there is hope for the remnant through whom Yahweh will fulfill His purpose. Again and again Isaiah calls the men of Judah to live by faith in God; to depend utterly upon Him in the midst of national crisis; for example (in free translation): *If you will not have faith, surely you will not stand firm* (chap. 7:9b); *He who has faith will not be in haste* (chap. 28:16b). The time will come when a king will reign in righteousness, the dawn of a new age of peace, *for the earth will be full of the knowledge of Yahweh, as the waters cover the sea* (chap. 11:9b). JAMES MUILENBURG,
Davenport Professor of Hebrew and Cognate
Languages, Union Theological Seminary, New
York.

ISAIAH, Book of, book of the Old Testament attributed to the prophet Isaiah (q.v.) although it includes prophecies by Second Isaiah and by other successors.

The prophets of ancient Israel were first of all speakers, and the oral nature of their oracles is stamped indelibly upon them. They address their contemporaries with "Thus says the Lord," or "The Lord said to me," or "These are the words which the Lord has spoken." It was only later that their words were written down and compiled. It is possible in some instances that the prophet had a hand in the formation of such "books," but by and large it was his disciples who preserved the traditions associated with their master. In some cases the compilation was prepared within a relatively short time after the words were spoken; in other cases it may have been many years. Other materials were later added which were believed to belong to the same prophetic tradition; thus we encounter considerable diversity in style and terminology and even of thought within the same book. We have an excellent illustration of this process in the Book of Isaiah. To the Isaianic corpus were added the poems of Second Isaiah or Deutero-Isaiah (Isaiah 40-55), which actually come from a period two centuries after Isaiah, the prophet of the 8th century B.C., because it was felt that he was perpetuating the same tradition as his predecessor. In these poems we have the same stress upon Israel's Holy One, upon the kingship of Yahweh, and upon His purpose in the forward movement of history. Then, later, following the same tradition, the prophecies of the successors of Second Isaiah were added (chaps. 56-66). The final stage of the book was a product of the exilic or post-exilic period. Similar processes are reflected in some of the other prophetic books, where the same general ordering of materials is seen.

The four great corpses—Isaiah, Jeremiah, Ezekiel, and the Book of the Twelve (the Minor Prophets)—are all compilations; indeed, they are in some instances compilations of compilations. The first task of the modern student, therefore, is to disintegrate the various collections in order to arrive at the original literary units. Then he must seek to establish the date and provenance of each unit, its literary type and form, and the purpose and nature of the passage. Finally he must endeavor to interpret it in the light of the historical situation in which it was first addressed to the men of Israel. Such an undertaking is the scientific approach to an ancient historical document, but it is also the appropriate way of dealing with a divine revelation which professes to be historical, a revelation relevant to a particular time and a particular people. It is obvious that the results of such an operation as we have been describing will present us with a book quite different from the one which appears in the Bible, for the materials will often be radically reordered to conform to the historical development of the literature.

As we have it before us today, the Book of Isaiah falls into three general divisions: (1) chapters 1-35; (2) chapters 36-39; (3) chapters 40-66.

The first of these divisions contains five sections: (1) chapters 1-12; (2) chapters 13-23; (3) chapters 24-27; (4) chapters 28-33; (5) chapters 34-35.

The third division has two sections: (1) chapters 40-55 and (2) chapters 56-66.

First General Division.—Section 1, Chapters 1-12.—The original nucleus of this compilation is Isaiah 6:1-9:7. It opens, like the books of Jeremiah and Ezekiel, with an account of the prophet's call (chap. 6), and is followed by a series of episodes dealing with the Syro-Ephraimite crisis (734-733 B.C.). Chapter 9:1-7 is denied Isaiah by many scholars; others assign it to a late period in his life. More recently, however, the tendency has been to accept it as genuine and to interpret it against the background of the ideology of the sacral kingship. The collection is certainly Isaiah's and may have circulated for a time as an independent collection. To this book were added the poem on the day of Yahweh (chap. 2:6-19), perhaps at a very early period; also chaps. 9:8-10:4 and 5:25-29, a remarkably vivid series of strophes concerning the imminent destruction of Samaria (722 B.C.); chap. 5:1-7, the song of the vineyard; chap. 5:8-24, invectives and threats. Chapter 1 is a gathering together of diverse materials, and verses 2-3 form an excellent introduction to the prophecy as a whole. Chapter 12, on the other hand, is a late eschatological hymn, probably placed in its present position for liturgical purposes.

Section 2, Chapters 13-23.—These chapters are distinguished by the word *massa'*, which appears some 10 times as a superscription. It is usually rendered "burden," or, in the Revised Standard Version (RSV), "oracle." Many of the oracles are addressed to the foreign nations—Babylon, Moab, Damascus, Egypt, and others. Much of the material does not belong to Isaiah. Among the materials which may be assigned to the prophet are chap. 14:24-27, the removal of the Assyrian yoke; chap. 14:28-32, an invective on the Philistines; chap. 17:1-11, the fall of Damascus (732 B.C.); chapter 19, a symbolic prophecy against Egypt; and chapter 22, two

utterances from different periods. The date of the collection as a whole is the postexilic period.

Section 3, Chapters 24-27.—This section is sometimes called "the little apocalypse." It is composed of eschatological prophecies (chaps. 24:1-3, 17-23; 25:6-8; 27:1, 12-13) and poems (compare the eschatological hymn of 25:1-5, 9-12). In vivid pictures it portrays the end of things, the threat of world destruction with the return of primeval chaos, and a prediction of the return of the Diaspora. While there is no general agreement as to the date of the section, it is certainly late, perhaps as late as the 4th century B.C. The attempt to date it in the late 2d century B.C. is shattered by its presence in the Isaiah manuscripts among the Dead Sea Scrolls (see *SCROLLS, THE DEAD SEA*).

Section 4, Chapters 28-33.—Like chapters 1-12, this section contains a considerable amount of genuine Isaianic material. Among the passages which have the best claim to authenticity are the following: chap. 28:1-22 (verses 1-4, an invective against Samaria; verses 7-22, an invective against priests and prophets); chap. 28:23-29, Yahweh's instruction to the farmer; chap. 29:1-8, beginning with "Ho Ariel, Ariel" (RSV), a threat expanded by a later promise; verses 9-15, three originally independent invectives; chap. 30:8-14, an invective and threat opening with the instruction to Isaiah to inscribe his words in a book "as a witness for ever" (RSV); chap. 31, directed to those who go to Egypt for help. This compilation is usually styled the anti-Assyrian cycle because with few exceptions all the oracles come from the anti-Assyrian period of 713-701 B.C. Following Hermann Gunkel, many interpret chap. 33 as a liturgy composed of different literary types.

Section 5, Chapters 34-35.—The two chapters are counterparts to each other, the one describing the destruction of Edom, the other the felicity of Zion. The theme of both is eschatological. It is held by some scholars that they were placed here as a conclusion to chaps. 1-33; others, like Charles Cutler Torrey, believe that they belong with chaps. 40-56 but have been separated from them by the narrative section (chaps. 36-39) in order to weave chaps. 1-33, 34-35, and 40-56 into a single book.

Second General Division.—Chapters 36-39.—This division is drawn from II Kings 18:13-20:19, although in a somewhat altered form. It has been inserted by the final compiler in order to include all materials associated with Isaiah. The psalm of Hezekiah (Isaiah 38:9-20) has been added to the tradition from Kings. The rest of the material belongs to the characteristic type of prophetic narrative (compare the Elijah narratives).

Third General Division.—Section 1, Chapters 40-55.—The section forms a literary unit composed, to be sure, of a number of separate poems. The dominating theme is eschatological. Yahweh is about to appear in history in a mighty act of redemption. The "prologue" takes place in the heavenly assembly where the great event is first announced (chap. 40:1-11). All the major themes of the sacred past are brought to bear upon the interpretation of the events that are now about to happen. The Servant of the Lord plays a role of central importance throughout, culminating in the poem on the Suffering Servant (chaps. 52:13-53:12). In many passages it is certain that the servant is Israel; in others (as in chaps. 40:1-

4; 42:1-6; 52:13-53:12; 55:4-9) there is disagreement as to the identification. Many believe he represents an individual; others identify him with Israel, as in the other poems. The section is to be dated about 550-538 B.C., the end of the Babylonian age.

Section 2, Chapters 56-66.—These poems have many striking affinities with Second Isaiah; for this reason a number of scholars believe that they are of the same authorship. A more probable view is that they were composed by Second Isaiah's disciples and followers. The eschatology of the section is more advanced, the literary style is often different, and the theology reflects a greater interest in the cultus. Chapter 56:1-8 is a prophetic torah concerning the admission of foreigners and eunuchs to the temple community; chaps. 56:9-59:21 consist of rebukes to several classes, interspersed with promises for fidelity; chaps. 60-62 describe the New Jerusalem; chap. 63:1-6 tells of the divine hero in Edom; chaps. 63:7-64:12 deal with confession; chaps. 65-66 set forth the contrast between the faithful and the apostates.

Bibliography.—The reader is referred to the relevant sections in the Biblical encyclopedias; the histories of Israel; Old Testament introductions, theologies, and Near Eastern parallels; also James Bennet Pritchard's *Ancient Near Eastern Texts Relating to the Old Testament* (Princeton 1930). Only the more influential and important works on Isaiah are listed below.

COMMENTARIES: Lowth, Robert (London 1778); Delitzsch, Franz Julius (Edinburgh 1873); Ewald, Heinrich (London 1875-81); Dillmann, C. F. August, ed. by Rudolf Kittel (Leipzig 1898); Marti, Karl (Tübingen 1900); Condamine, Albert (Paris 1905); Wade, George Woosung (London 1911); Skinner, John (Cambridge, Eng., and New York 1915); Duhm, Bernhard (Göttingen 1892, 1922); Schmidt, Hans (Göttingen 1923); Feldmann, Franz (Bonn 1925-26); Smith, Sir George Adam (London 1888-90, 1927, New York 1928); Kissane, Edward J. (Dublin and New York 1941-43); Gray, George Buchanan (New York 1947); Hertrich, Volkmar (Göttingen 1950); Scott, Robert B. Y. (New York 1956).

COMMENTARIES DEALING EXCLUSIVELY WITH ISAIAH: 40-55 or 40-66: Torrey, Charles C. (New York 1928); Prockosh, Otto (Leipzig 1930); Volz, Paul (Leipzig 1932); Fischer, Johann (Bonn 1937-39); Muilenburg, James (New York 1956).

OTHER WORKS: The literature is so vast as to defy enumeration. For a good bibliography on the Servant of the Lord, see North, Christopher R., *The Suffering Servant in Deutero-Isaiah, an Historical and Critical Study*, pp. 222-235 (New York 1948).

JAMES MUILENBURG,
Davenport Professor of Hebrew and Cognate Languages, Union Theological Seminary, New York.

ISAR, ē'zār, river, Germany, in Bavaria. It rises just north of Innsbruck, Austria, and flows generally north and northeast in Bavaria for about 163 miles, through Munich and past Landshut, to join the Danube near Deggendorf.

ISAROG, ē-sā-rōg', extinct volcanic mountain peak in the Philippines, on Luzon Island, in Camarines Sur Province, 10 miles east of Naga. It is 6,482 feet high. Sulphur is mined on it.

ISAURIA, i-sō'ri-ā, an ancient district of southern Asia Minor, bordering ancient Pisidia and Cilicia. It lies north of the Taurus Mountains, in what is now south-central Turkey. It was a wild region where wandering tribes lived by plunder. Partially subdued by Rome in the 1st century B.C., it was never entirely conquered until the arrival of the Seljuk Turks in the 11th century A.D. Two Isaurians became Byzantine emperors, Zeno (r. 474-491) and Leo III (r. 717-741).

ISCHIA, ĭs-kĭ-à, It. ěs-kyä (anc. PITHECUSAE and AENARIA), island, southern Italy, in Campania, near the northern entrance to the Bay of Naples. A channel eight miles wide, in which lies the island of Procida, separates Ischia from Cape Miseno (q.v.) on the mainland. The island, about five miles long and four miles wide, covers an area of 18 square miles. The coast is deeply indented and the terrain mountainous, reaching the highest point (2,588 feet) in Mount Epomeo. Ischia is of volcanic origin and suffered from severe eruptions, the last one in 1301 or 1302. Strictly connected with the past volcanic activity are the numerous warm mineral springs and the frequent earthquakes—the worst one in 1883 practically destroying Casamicciola (q.v.). Ischia has been a favorite resort since Roman times, because of the therapeutic value of its mineral springs, and because of its equitable climate, luxuriant vegetation, and enchanting scenery. Catering to tourists, cultivating grapes and other fruit, and wine processing are the chief occupations. The principal towns are Ischia (11,416), Forio (7,209), and Casamicciola (4,983). On a small islet off the town of Ischia stands an imposing medieval castle and along the coasts are towers erected as a defense against Turkish pirates who ravaged the island during the 16th century. Pop. (1961) 34,213.

ISEO, Lago d', ě-zâ-ô (anc. SEBINUS LACUS), lake, northern Italy, in the Alpine foothills of Lombardy, at an altitude of 610 feet. It is formed by the Oglio River that enters in the north and leaves from the south. Long and narrow, the lake has an area of 23.5 square miles, a length of about 15 miles, a maximum width of 3 miles, and a maximum depth of 820 feet. The western shore is in the Province of Bergamo, the eastern shore in the Province of Brescia. In the center of the lake is an island, Monte Isola (Montisola). The shores are covered with olive groves and the waters abound in fish. Towns on its shores are Lovere and Pisogne in the north, and Iseo and Sarnica in the south.

ISÈRE, ě-zâr', department, France, in the southeast, part of the old province of Dauphiné, bounded north and west by the Rhone, east by Savoy, and south and southeast by Drome and Hautes Alpes. Its area is 3,178 square miles, about 50 percent of which is arable and 20 percent forest land. The surface is level in the north, but becomes very mountainous toward the south, where the scenery is magnificent. It is drained by the Rhone, and its tributary streams, the Isère, Drac, and Romanche. The department is rich in minerals. Coal, iron, lead, silver, gold, and marble are mined and the forest products are of importance. Gloves, paper, and silk are manufactured. Grenoble is the capital. Pop. (1962) 729,789.

ISÈRE RIVER, river, southeast France, which takes its rise in Savoy at the foot of Mount Iseran, flowing generally southwest through Savoy and through the departments of Isère and Drome, and joining the Rhone about six miles above Valence. Its entire length is about 190 miles, for the last 70 of which it is navigable.

ISERNIA, ě-zĕr'nyâ, town, southern Italy, in Campobasso Province, Abruzzi e Molise, 23

miles west of Campobasso. Wool textiles and lace are the chief products. Landmarks include ancient walls, a Roman aqueduct, and a cathedral (1837). A Samnite town, it flourished as a road center in Roman times. Pop. of the commune (1961) 12,781.

ISFAHAN, ĭs-fâ-hân', Iran, city 210 miles south of Teheran, former capital of the country. It is situated in the midst of an extensive plain watered by the Zaindeh Rud. At the heart of the city is a great square known as the Maiden-i-Shah, formerly encircled by a canal. Notable buildings still standing include a royal mosque built by Shah Abbas I, the royal palace, and a lofty archway which leads into magnificent gardens. The principal industries of the city include the manufacture of carpets, woolen and cloth textiles, and matches. There is also an extensive trade in leather goods, silver filigree work, and lacquered products. The city is the center of the activities of the Church Missionary Society (of the Anglican Church) and of Iranian adherents of the Roman Catholic Armenian rite.

Known to the ancients as *Aspadana*, the city reached its greatest prosperity under Shah Abbas I—early in the 17th century. Jean (later Sir John) Chardin (q.v.), who resided at Isfahan from 1664 to 1681, reported that the walls were 24 miles in circuit and contained 162 mosques, 48 colleges, 1,802 caravansaries, and 273 public baths. After the Afghans captured Isfahan in 1722 the capital was removed to Teheran; although soon retaken by Nadir Shah the city declined gradually in importance. During World War I, the Russians occupied it for a short period in 1915–1916 and then were replaced by a British force. Pop. (1960) 246,600.

Consult Lockhart, L., *Famous Cities of Iran* (London 1939).

ISHAM, ĭ'shâm, Samuel, American painter and writer: b. New York, N.Y., May 12, 1855; d. Easthampton, June 12, 1914. After graduating at Yale University in 1875 he studied law, but turned to painting after admission to the bar. He studied art in Paris and later in the United States, and in 1906 was made a member of the National Academy. His fame rests, however, on his *History of American Painting* (1905), which is notable for its sympathetic and just appreciation.

ISHII, ě'shĕ-ě, Viscount Kikujiro, Japanese diplomat: b. Chiba, Japan, 1866; d. Tokyo, May 25, 1945. Soon after taking a law degree at the University of Tokyo in 1890 he joined the staff of the Japanese legation in Paris, and from 1896 to 1900 he was consul in Chemulpo, Korea. In the latter year he was secretary of the legation in Peking (Peiping), during the siege by the Boxers (q.v.). He negotiated with the United States government in 1907 the agreement restricting emigration of Japanese to the United States, and the same year investigated the anti-Japanese riots in British Columbia. From 1912 to 1915 he was ambassador to France, then becoming minister of foreign affairs; in 1916 he received his viscountcy. In 1917 he went to Washington, D.C., as special envoy, there negotiating the Lansing-Ishii agreement with Robert Lansing, secretary of state, which recognized that Japan had special interests in China. Besides being versed in French, he was a fluent speaker

and writer in English. From 1920 to 1927 he again served as Japanese ambassador in Paris. During this period he took an active part in the work of the League of Nations, becoming president of its council in 1923 and once more in 1926. He retired from public life in 1927. His death occurred in an air raid by United States planes during World War II.

ISHIM, i-shim', Soviet Union. (1) Town of the Omsk Region, Russian Soviet Federated Socialist Republic, on the river of the same name, 180 miles northwest of Omsk. Founded in 1630, it is an agricultural center. Pop. 18,153. (2) River, rising in the north central area of the Kazak SSR and flowing northwest and north to join the Irtysh after a course of 1,330 miles.

ISHMAEL, ish'mā-ēl, from Hebrew, signifying "God hears," was eldest son of Abraham and Hagar, his handmaid (Genesis 16:15, 16). Of him it was foretold (Genesis 17:18, 20) that he would beget 12 princes and become a great nation—a promise repeated (Genesis 21: 18) to his mother when, driven from home by Sarah's attitude, both she and the lad were wandering in the territory south of Beersheba and death by thirst was near. Later he became an archer, dwelling in the wilderness of Paran, where Hagar "took him a wife out of the land of Egypt" (Genesis 21:21). In a later chapter (Genesis 25:9-18) it is stated that he died at the age of 137, having had, like Jacob, 12 sons, progenitors of 12 tribes that dwelt from "Havilah unto Shur, that is before Egypt, as thou goest to Assyria." Apart from the Biblical record few of the names have historical associations. Among various identifications more or less plausible may be mentioned Nebaioth with the Nabataeans, Yetur with Ituraea, whose archers were early Roman mercenaries; Kedar with the Kidru of the Assyrian inscriptions.

In the Midrash, the rabbis show how Sarah's disposition to Hagar was at first kindly but that Hagar's actions compelled a change. Ishmael's intercourse with Isaac is told with considerable minuteness at times, as when he invites his five year old brother to a contest with the bow and arrow and aims at the child in his duplicity. When Ishmael was at the point of death, God heard his prayer and caused a well to bubble forth that later was to refresh the Israelites on their journey through the wilderness. In Arabic lore Ishmael is no less a picturesque figure, and the Koran adds to his importance for it calls him a prophet (Koran 19:55). His son Kedar is reported to have been an ancestor of Mohammed. It is characteristic of Mohammedan tradition that Ishmael should be offered as a sacrifice instead of Isaac. We cannot tell historically how far the descendants of Ishmael entered Arabia and settled there, with its mixed population of thousands of years. Possibly the Bedouins in the deserts between Sinai Peninsula and the Persian Gulf are more entitled to claims of Ishmaelitic origin with their primitive and patriarchal form of life and ancient traditions.

ISHMAELITES. See **ISHMAEL**.

ISHPEMING, ish'pē-mīng, city, Michigan, in Marquette County, 14 miles west of Marquette, served by the Duluth, South Shore, and Atlantic, the Lake Superior and Ishpeming, and

the Chicago and Northwestern railroads. Machinery is manufactured for use in the neighboring great iron ore region. Settled about 1856, it received its first charter in 1857. The government is by city manager and council. Pop. 8,857.

ISHTAR. See **BABYLONIA**.

ISIDORE OF SEVILLE, iz'ī-dōr sē-vīl' (Lat. ISIDORUS HISPALENSIS), Spanish prelate and scholar; b. 560?; d. April 4, 636. In 600 he was appointed archbishop of Seville. A leading churchman of his day, he exerted a great influence upon the thought and literature of the whole Middle Ages. His *Originum seu Etymologiarum Libri XX* (known in English as *Etymologies*) was a great encyclopedic work. Consult Brihaut, E., *An Encyclopedist of the Dark Ages* (New York 1912).

ISINGLASS, i'zīng-glās, a form of gelatin (q.v.), whitish, firm in texture, and of great purity, prepared mainly from the sounds, or air bladders, of various species of fish, especially of the Russian sturgeon and, in the United States, of cod, sturgeon, and hake. In some cases the skins are also used for this purpose. Besides Russia, from which it had been principally obtained, the United States and Canada, Brazil, and the East Indies furnish considerable quantities. It is the basis of Russian glue, preferred to all other kinds for strength. It is used in making court plaster, cement, mock pearls, and many other articles; in clarifying fermented liquors for improving soups and jellies; and as sizing for linens, silk, gauzes, and other fabrics.

ISIS, i'sis, the principal goddess of the Egyptians, the sister and wife of Osiris (q.v.), representing the moon, as Osiris did the sun. The Egyptians believed that Isis first taught them agriculture. She is represented in various forms. In one she has the form of a woman, with the horns of a cow, as the cow was sacred to her. She is also known by the attributes of the lotus on her head, and the sistrum in her hand, a musical instrument which the Egyptians used in the worship of the gods. She is often accompanied by her infant son Horus. In one celebrated Egyptian statue she was shown with her face veiled. It was she who, by wiles, learned the name of the great Ra (Re) which no one else knew. She is also represented in legends as mourning for Osiris with her sister Nephthys. Herodotus identifies her with the Greek Demeter. The same author states that the worship of Isis and Osiris was the only common ritual throughout Egypt. She was particularly worshipped in Memphis, but at a later period throughout all Egypt. From Egypt her worship passed over to Greece and Rome, in about the 3d century B.C.

ISIS AND SERAPIS, Temple of, a structure of ancient Rome, situated in the Campus Martius. It was erected from Egyptian materials and in Egyptian style, and the approach was lined with many monuments brought over from Egypt. Of these there remain in Rome three obelisks, and the Nile statuary group, the latter in the Vatican Museum. The Tiber statue has reposé in the Louvre since 1803. Various smaller pieces have been recovered.

ISKENDERUN, is-kên-dêr-ôôn', Turkey, seaport of the vilayet of Antakiya, in a gulf of the same name at the northeast extremity of the Mediterranean; formerly it was known as ALEXANDRETTE or ALEXANDRETTA. Much of the seaborne trade of northern Syria passes through the port, which has rail connection with the main Turkish system. Alexandrette formed part of the Ottoman Empire down to the close of World War I, when it was occupied by French troops. In 1920 the seaport was incorporated in the French mandate of Syria, and the sanjak (district) of which Alexandrette was the capital was granted considerable autonomy in 1937; in 1938 the name of the sanjak was changed to Hatay, and in 1939 Hatay was transferred to Turkish sovereignty. Hatay became part of the vilayet of Antakiya (Antioch), and Alexandrette resumed its earlier Turkish name of Isken-durun. Pop. (1940) 13,997.

ISLA, ês'lâ, José Francisco de, Spanish Jesuit preacher and satirist: b. Vidanes, province of León, April 24, 1703; d. Bolonia, Nov. 2, 1781. He entered the Jesuit order at the age of 16, and became a teacher of theology and philosophy in various Jesuit colleges. Best known of his writings was the picturesque novel entitled *Historia del Famoso Predicador Fray Gerundio de Campazas, alias Zotes* (1758), a witty satire on the extravagances of the preachers of his day. The ridicule cut so deep that it was never forgiven by some of his fellow preachers; and they raised up for him powerful enemies who, in 1760, succeeded in having the sale of *Fray Gerundio* prohibited. Among his most popular translations was *The Adventures of Gil Blas de Santillana*, the French work by Alain René Lesage (q.v.). Other works of Isla included *Triunfo del Amor y de la lealtad: Dia Grande de Navarra*, which satirized the accession ceremonies of Ferdinand VI; and the satire *Cartas de Juan de la Encina*. His *Sermones Morales*, published posthumously in 1792-1793, testifies to his excellence as a preacher.

ISLA DE PINOS. See ISLE OF PINES.

ISLAM is a system of belief and practice established by Mohammed (q.v.), the Arabian prophet. To the Westerners it is better known under the name Mohammedanism, to which its professors prefer the other term. They themselves would also rather be called Moslems than Mohammedans. Mohammed died in 632 A.D. in Medina. Today there are some 300 million followers of his, forming the bulk of the population of Northern Africa and Western Asia, and extending all the way through India into Malaya, the East Indies, and the Philippines. Every seventh man living today is a Moslem.

Religion of Surrender.—The word Islam (*islām*) means surrender, submission (to the will of God). It occurs several times in the Koran (q.v.) in its literal as well as technical meanings. The form is an infinitival noun from a stem used in the Koran in connection with the submission of Abraham and his son, at the attempted sacrifice by the father, to the Divine will (37:103). It is presumably this act that first prompted Mohammed to coin the new designation for his religion. "This day have I perfected your religion for you and completed My

grace unto you; I have chosen for you as religion *al-Islām*" (5:5). "Verily the religion with God is *al-Islām*" (3:18).

Pervades all Domains of Life.—In the Western mind a clear distinction is normally drawn between two spheres of life: The spiritual, comprising religion; and the secular, comprising political, economic, social, and cultural activities. That is not the case with the Moslem. To him Islam embraces all departments of life, a kind of totalitarian system with control over all the varied domains of human activity. This is a unique feature of the Islamic religion. What Mohammed founded was not a religion only, but a society in which the religious, the political, and the social are inseparable.

Islam differs from Christianity in another important aspect. It has no ordained priesthood, no clerical hierarchy, and no mystic sacraments. It is a lay religion, a practical one, with no complicated theology and no unattainable ideals. As such, it has special appeal to the societies that are still on a low cultural level and makes progress where Christianity fails.

Viewed from our standpoint, the structure of Islam may be analyzed under three main headings: Religious, social, and political. The religious structure is composed of dogmas of belief and acts of worship.

Five Dogmas.—The first and most important article of Islamic faith relates to the oneness of God. It is expressed in the formula: *La ilāha illa-l-Lāh* (47:21), no god but Allah. This is one of the most often repeated formulas in the Arabic language. Its concept lies at the very foundation of the entire structure. Moslems pride themselves on being the only *muwahhidūn*, unitarians. God is one, He is pre-existent, omnipotent, omniscient. He is the creator of all things. "He is God, the one; God the eternal. He begets not and is not begotten; nor is there like unto Him any one" (112).

In the Koran He is again and again described as "powerful over all things," "knowing all things." But He is also gracious, forgiving, merciful, and compassionate. As the ruler of all things He may do whatever seemeth good in His sight; yet He is a just God. He punishes only where punishment is due. Humble submission to His will has throughout the ages constituted the essence of Islamic piety.

Closely joined with this dogma is the second one, expressed in the formula *Muhammadsun rasūlu-l-Lāh*, Mohammed is the messenger of God. The two are usually repeated together. Mohammed, according to the learned system, was not divine. He was a messenger, a warner, and a prophet. As a prophet he was in the tradition of Noah, Abraham, Moses, and Christ. But he was "the seal of the prophets" (33:40), the last and therefore the greatest among them. He was the sole channel of revelation for his own time and generation, and the last apostle for all times and all generations. His dispensation supplements and, wherever necessary, supersedes all earlier ones. He performed no miracles unless it be that of the Koran. He was the means through which the Koran was revealed.

The third article of faith relates to the Koran. This book is the uncreated word of God. It was dictated piece by piece in Arabic through Gabriel. As such, it should be studied and recited in the original tongue. Only the Turks have recently violated this rule. When

quoted, a koranic passage is introduced with "saith God." In its Arabic form, it is an exact replica of a divine book preserved in the seventh heaven, where it is well guarded. None therefore should touch it unless in a state of purity, which involves ablution (56:76-8; 80:13-15).

Then comes the belief in the angels, arranged in a hierarchy and headed by Gabriel, bearer of the revelation (2:91). Angels were created long before the world and are of finer material. They perform different functions. They intercede for man (42:3), act as guardians (13:12), and support the throne of God (69:17). The names of many of them, as recorded in the Koran and Moslem tradition, are of undoubted Hebrew origin.

Hell and Heaven.—The last fundamental article of faith is belief in a judgment day, immortality of the soul, reward for the righteous, and punishment for the wicked. "The last day," "the last hour," "the day of judgment" will be ushered in by certain extraordinary signs. On it, all actions shall be weighed in the scales. "Those whose scales are heavy are the successful ones; and those whose scales are light shall lose their souls and abide in hell forever" (23:104-5). The sin for which one is punished may be moral or ceremonial. One sin is unpardonable, that of *shirk*, associating other deities with the one God (4:51, 116). Later theologians distinguished between "little" sins, which are inherent in man's nature, and "great" sins, for which a Moslem, if he does not repent, will be consigned to hell-fire. Immediate expectation of a day of judgment and fear as a motive of piety were stressed before the time of Mohammed by Syrian Church fathers.

To Mohammed, as revealed in the Koran, the last day was not a hazy possibility in a remote future but an imminent certainty. On it, all the dead shall rise. Resurrection entails the body. Both reward and punishment are of the sensual type. Hell is portrayed as God's kindled fire, which shall verily rise above the wicked like a vault on outstretched columns (104:5-9). There the damned shall be "scorched by burning fire, made to drink from a boiling fountain. No food shall they have save the fruit of a bitter thorn, which doth not nourish nor appease their hunger" (88:4-7). Such passages provided material for the fertile imagination of Moslem commentators, who worked out elaborate and fantastic schemes of torment. They arranged hell in seven divisions, and consigned different evil doers into different divisions varying in the degree of torture.

Paradise is also painted in materialistic colors. In it the faithful is to enjoy all the delights and luxuries nearest to the heart of a denizen of the desert. The general picture is that of an oasis, a garden, with shady trees, running streams, and all facilities for rest, comfort, and enjoyment. Several passages in the Koran dilate on the scene: "He [God] hath awarded them [the believers], for all that they endured, with Paradise and silk attire, reclining therein upon couches. Naught shall they know of [hot] sun or bitter cold. Its shades shall close upon them, and low shall its fruits hang down. Vessels of silver are brought round for them, and goblets like flagons, flagons made of silver whose measure they themselves shall mete. There they are given to drink of a cup whereof the mixture is of ginger from the fount named *salsbil*. There

go round among them boys of everlasting youth whom, when thou seest, thou wouldst take for scattered pearls. And when thou lookest at this, thou wilt see bliss and high estate. Their raiment will be fine green silk and gold brocade. With silver bracelets they will be adorned, and their Lord will give them drink of a pure beverage" (76:12-12).

Belief in God's absolute decree is often treated as a sixth article of faith. The Koran is explicit in its teaching that everything that happens to man has already been fixed by God: "Naught befalleth us save that which God hath decreed for us" (9:51); "No soul can ever die except by Allah's leave, in accordance with what is written and determined" (3:139).

Five Religious Duties.—Islam is not only a system of faith but one of practice. It enjoins on its followers five acts of worship, religious duties, often termed the pillars of faith.

The first pillar involves a verbal profession of the unity of God and the prophethood of Mohammed. It is not enough for a Moslem to believe in God; he must declare his belief: No God but Allah; Mohammed is the messenger of Allah. This formula is of such importance that once a non-Moslem recites it, he is to all intents and purposes a believer. In order to be a good believer he should then proceed to the practice of the other acts.

The second act of worship is prayer. A good Moslem could informally commune with God any time of day or night, but he is obligated to practice five legally prescribed and defined prayers. This formal prayer is made with the utmost decorum. Preparatory to it the worshiper should go through certain ceremonies of purification and ablution (5:8-9). Every mosque is provided with facilities for such washings. Sand or dust would do in the absence of water. After going through the required ablutions the worshiper stands straight with his face toward Mecca, assumes a fixed position, recites certain formulas, and repeats a number of genuflections. The five times are early dawn, noon, mid-afternoon, sunset, and night. It is remarkable that in no single Koranic passage are the five periods mentioned. Even when added, the periods seem to be four. But all commentators agree that the *masā'* period includes two: sunset and evening (30:16-17).

The approach of each hour of prayer is heralded by the call to prayer, made by the muezzin (q.v.) from the minarets:

God is most great! (repeated four times)
I testify there is no god but Allah; (twice)
I testify Mohammed is the messenger of Allah. (twice)
Come to prayer; (twice)
Come to salvation. (twice)
God is most great! (twice)
There is no god but Allah.

Assuming a fixed posture while engaged in formal prayer, as well as bending the knees and prostrating oneself, were a well-known practice among monks and hermits of the Syrian Christian Church. An early Arabic poem refers to a monk's forehead as hard as a camel's knee on account of religious prostrations. Islam, however, regularized and popularized the practice. An orthodox Moslem is, as a rule, not ashamed of his God. He may be seen indulging in this devotional exercise in the bazaar, the field, or the modern street car.

Friday noon is the only prescribed congregational prayer. In it the members meet in

mosques, devoid of pews and unornamented with pictures, arrange themselves in standing rows, and follow the leader (*imām*) in the conduct of the service. The leader delivers a sermon (*khutbah*) in which he invokes God's blessing for the success of Islam and the prosperity of the rulers and the caliph (in cases where there is one).

Almsgiving, the third duty of the believer, is often joined with prayer in the koranic injunctions. "Observe prayer, pay the alms, and kneel with those who kneel" (2:40; cf. 2:77, 9:5). In the early days of Islam alms were collected from believers by officials appointed for that purpose, and were used for building mosques, helping the needy, and in other ways promoting the cause of the religion. With the spread of Islam this procedure was necessarily abandoned; giving became a personal affair. The obligation to give is nevertheless universally recognized by Moslems. Even those among them who neglect other duties may not neglect this.

Fasting is the fourth religious duty prescribed by Islam. The month of Ramadan is devoted for this purpose. In it the faithful are supposed to abstain from food, drink, and other indulgences from dawn till sunset (2:183). Ramadan was chosen because it was the month in which the Koran was revealed. Being a lunar month it rotates around the year, and fasting in it becomes arduous when it falls in summer. Exemptions are made in favor of the feeble, the sick, and the traveler (2:181). To fast at other times is meritorious but not obligatory.

Both Christians and Jews practiced fasting before Islam. Besides regularizing and emphasizing it, Islam put a somewhat different interpretation on it. The object of Moslem fasting is not so much to mortify the body as to atone for evil deeds and to commune more intimately with God.

Pilgrimage.—The fifth requirement of practical religion is the pilgrimage to the holy places in Arabia. Once in a lifetime the Moslem, whether man or woman, is supposed to undertake the religious pilgrimage at a stated period: "It is a duty toward God, incumbent on those who are able, to visit this House" (3:91). Women with no male relatives to accompany them, lunatics, and those who cannot afford the trip are exempted. The time is fixed in the first half of the month of *dhu-al-Hijjah*. In that period the caravans from Syria, Egypt, Iraq, and other parts of the Moslem world converge on Mecca. In 1946 the estimated number of pilgrims was 50,000. Before World War II it rose as high as 250,000.

That pilgrimage to sanctuaries is an ancient Semitic rite is indicated by its prescription as an indispensable duty in the old part of the Pentateuch (Ex. 23:14). But, as in the case of other institutions borrowed by Islam, it was modified and crystallized. When the pilgrim approaches the sacred area around Mecca, he goes through the ablutions, puts on a special seamless garment, and proceeds with the other pilgrims. Guides instruct him as to the proper procedure. While in this state he cannot even trim his nails or kill a flea. First he must encircle the Kaaba (q.v.) seven times, kissing the Black Stone each time. This is a meteoric stone set in the southeast corner of the Kaaba and, like it, a relic of pre-Islamic heathenism. Moslem tradition says that it came down from Paradise, and that on

the judgment day it will give evidence in favor of those who kissed it. Other prayers and ceremonies follow. Then the pilgrim must run seven times between two hills, al-Safa and al-Marwah, repeating certain formulas (2:153). Later he visits the Valley of Mina and Mount Arafat, where more prayers are recited and a sermon is preached. On the way to Mina each pilgrim casts stones at three pillars, seven stones at each. The stones are, according to Moslem explanation, really thrown at Satan, who appeared on this spot to Abraham. A sacrifice of a sheep or goat closes the performance. The rich may sacrifice a camel. It is considered meritorious to give the meat of the sacrificed animal to the poor. The day is celebrated throughout the world of Islam as 'Id al-Aḍḥa (the feast of sacrifice).

The pilgrim at last shaves, discards the special cloak, and reverts to the secular condition. While in Mecca he usually drinks from the water of Zamzam, the sacred well within the precincts of the mosque, supposed to be the one from which Hagar and Ishmael drank when lost in the wilderness. Before returning home the pilgrim should do homage at the tomb of Mohammed at Medina. He is entitled to the proud designation of *hājj* (pilgrim) before his name.

Holy War.—The obligation of waging holy war (*jihād*) has been raised to the dignity of a sixth pillar of faith by one of the Islamic sects. Moslem ideology divides the world into two zones: the abode of Islam, where peace prevails, and the abode of war, which includes all the non-Moslem domain. It is further considered obligatory on the Moslem to keep on pushing the wall that separates these two zones until all lands are brought under the banner of Islam. The ordinary greeting between one Moslem and another, no matter what their languages may be, is the Arabic *as-salāmu 'alaykum*, peace be to you!

The koranic passages in support of the holy war theory are not so explicit. This is one of the most elaborate among them: "Fight in the path of God against those who fight against you, but be not the aggressors; for verily God loveth not the aggressors. And slay them wherever ye find them, and drive them out of the places whence they drove you out, for persecution is worse than slaughter. But if they desist, then verily God is forgiving, merciful" (2:186-8).

Social Structure.—From analysis of the religious structure, we now proceed to that of the social structure of Islam.

Foremost in the koranic legislation on the social side is the consideration of all those within the fold of Islam as one brotherhood. "The believers are naught else but brothers" (49:10). The earliest biographer of Mohammed quotes from a sermon which the Prophet delivered at the last pilgrimage he made: "Know ye that every Moslem is a brother unto every other Moslem, and that ye are now one brotherhood." Until then blood relationship was the cohesive binding element in Arabian society. Now this is replaced by a new cementing element—faith. In its historic evolution the Moslem community fell short of this ideal, but Pan-Islam is still, until the present day, a conscious force in the lives of Moslems. It transcends race, color, or nationality. Perhaps more than any other religion, Islam has succeeded in breaking down ethnic and provincial barriers.

Marital Laws.—Another important part of social legislation relates to marriage. Islamic marriage laws are quite liberal. "Marry of the women who seem good to you, two, or three, or four; and if ye fear that ye cannot be equitable, then only one, or what your right hands possess" (4:3). The last clause authorizes using female slaves as concubines. In this legislation Islam restricted polygamy rather than introduced it; but while restricting it, it put the religious label on it and froze it forever after. The modernized Moslem society has outgrown this legislation in favor of monogamy.

The believer is commanded to practice restraint and chastity and to treat his wives with kindness. Women are enjoined to be decent, to lower modestly their glances, and to display their charms only to their husbands and immediate relatives. This hardly involves the duty of veiling or confinement in a harem, both ancient Semitic institutions antedating Islam.

The statutes relating to divorce (2:226-38, 4:24) enable a husband to repudiate his wife without any misbehavior on her part, even without assigning a cause. Divorce is effective if expressed by one who is sound in mind and mature of age. But there are conditions to be fulfilled. The husband should wait for a prescribed time, to be sure that the wife is not pregnant, and should pay the fixed dowry. The period of waiting may be intended not only to remove all doubt about the real parenthood of a child, but to give the man an opportunity to change his mind in case of a hasty decision. The repeated admonitions to observe the divorce regulations indicate that the details were not previously known. Islam gives the wife the right of dissolving the marriage bond under certain conditions, a right she never enjoyed before.

The morality proclaimed by Mohammed is largely of social character. The koranic legislation in favor of the poor, the orphan, the sick, the stranger, and the destitute is copious and adequate. Here is a sample passage: "Unto your parents show kindness, and unto kindred and orphans and the needy, and unto the neighbor who is a kin and the neighbor who is a stranger, and unto the fellow traveler and the wayfarer, and whom your right hands possess" (4:40). The Prophet evidently never forgot that he himself was once an orphan, and was poor. Almsgiving, as noted above, was raised by Islam to a position of pre-eminence, along with prayer and fasting.

Slavery is authorized by Islam, as is evident from the last phrase in the passage quoted above, but humane treatment is enjoined throughout. Mohammed found slavery as an established institution in pre-Islamic heathenism, as well as in the Jewish communities, and recognized its legitimacy. Moslem men, as noted above, were authorized to use their female slaves as concubines. If one gave birth to a child, she usually became a freedwoman. Whenever a slave was in a position to redeem himself it was the duty of the Moslem master to grant emancipation (24:33). More than that, manumission has been treated throughout the Islamic age as something especially pleasing in the sight of God and regarded as an expiation for sin. Moslem history is rich in cases where masters sought God's favor through freeing slaves, sometimes going first through the trouble of purchasing them for the sake of enfranchising them. According to the strict law, no Moslem

could enslave a fellow Moslem. If a slave adopts Islam, freeing him is meritorious but not obligatory.

Prohibition.—Other interesting parts of koranic legislation relate to drinking wine and to gambling. In one passage, the prohibition is explicit and absolute: "O ye who have believed, wine, games of chance, idols, and divining arrows are nothing but an infamy of Satan's handiwork. Avoid them so that ye may succeed" (5:92). In another passage, the prohibition is not so final: "They question thee concerning wine and games of chance. Answer: In both there is great sin, and also some utility for men; but their sinfulness is greater than their usefulness" (2:216).

Other Islamic prohibitions relate to food. Especially interesting among these is one involving pork (5:4), which should under no conditions be eaten. Any flesh that is eaten must come from an animal killed in a prescribed way.

Non-Koranic Sources.—For a full comprehension of Islamic religion in its varied aspects, and particularly in its social and political ones, a study should be made not only of the Koran but also of the practice and sayings of Mohammed as portrayed in the *Sunnah*. Basically, the term means "path," "way." First applied to the way Mohammed taught by word or deed, *Sunnah* was then stretched to include the way his immediate followers acted, and later to the way of life pursued by the Moslem community at large.

The *Sunnah* is recorded in books entitled *hadith*, "communication," "narrative," "tradition." There are six authoritative collections of Moslem tradition. They constitute, next to the Koran, the most important source of Moslem religion, law, and practice. Then there is the established custom which conditioned the social and political development of Islam as it spread, and which contributed new elements to its social and political structure.

Certain universally accepted practices have no sanction in the Koran. The doctrine of the sinlessness of the prophets, including Mohammed, is not koranic but nevertheless is orthodox, as is the doctrine of his intercession on the day of judgment to the exclusion of all other prophets. The cult of the dead and the veneration of saints are contrary to the spirit of Islam, with its insistence on strict monotheism, but are practiced today all over Islam with the exception of its Wahhabi section. Circumcision is not even mentioned in the Koran, and yet it has been considered throughout all Moslem generations as the chief initiatory rite for converts, corresponding to Christian baptism. The custom is a very ancient one, and was practiced by Hebrews, Aramaeans, and other Semites.

Political Structure.—For our knowledge of the political structure of Islam we have to depend almost entirely upon non-koranic sources. The nearest approach in the Koran to what might be termed civic or state legislation is a general behest to the believers: "Obey God and obey the messenger and those of you who are in authority; and if ye have a dispute concerning any matter, refer to God and the messenger, if ye believe in God and the last day" (4:62). It was this command to obey "the messenger" that later sanctioned the use of the *Sunnah* as the second major source of authority in Islam.

Caliphate.—The most important political institution is the caliphate, succession to Mohammed. On this the Koran is silent. For successor, Mohammed could have one who performed his functions only as a leader, ruler, judge, and commander in chief of the army, but not as a prophet; he, being the last of the prophets, could have no successor as such. As long as Mohammed lived, Islam was a theocracy, "a community of God," a state under the direct government of Allah through His Prophet. With his death, revelation forever ceased. In his prophetic function Mohammed, therefore, could have no substitute. Only the Fatimid caliphs of Egypt (909-1171), who were extreme Shi'ites, were considered by their followers as semidivine rulers of a theocratic state.

The unexpected death of Mohammed in 632 left the community in a state of confusion bordering on consternation. At his death, he had no living son. Even if he had, it would not have made much difference probably, as Arabian practice did not justify hereditary succession into positions of leadership, unless the son was the best qualified candidate. Nor did Mohammed designate a successor. The Shi'ites, however, maintain that he did, and that the designee was his son-in-law, Ali. But when the elders got together they elected the aged abu-Bakr, a kinsman and early believer, caliph. Abu-Bakr started the first series of caliphates, which was patriarchal in character, and used Medina as capital. In 661 the capital was shifted to Damascus and a new series, the Omniad (Umayyad), was inaugurated. In 750 the Abbasid caliphate superseded the Omniad; shortly after that, Baghdad replaced Damascus as the capital.

Caliphal Qualifications.—Moslem legists stipulate that the caliph should be a male, descended from Koreish, sound in body and mind, mature in age, learned in law and religion, and capable of defending Islam. In practice, however, little regard was paid to these stipulations. The last caliphate was that of the Ottoman Turks, who were not even Semites. This caliphate was abolished by the Kemalists in 1924. Since then, several Pan-Islamic conferences have been held to revive this institution, but to no avail. Among the caliphal privileges is that of declaring a holy war, a privilege which was exercised by one of the last Ottoman sultans, Mohammed V, when Turkey entered World War I in 1914, but resulted in no action whatsoever.

Criminal Legislation.—The criminal legislation of the Koran, which is meager, follows ancient Semitic lines. It was revealed as different occasions arose, and constituted no organized comprehensive system. "We have prescribed for thee therein: A life for a life, an eye for an eye, a nose for a nose, an ear for an ear, and a tooth for a tooth, and for wounds, retaliation. But whoso forgoeth it, it shall be expiation for him" (5:49). "As for the thief, both male and female, cut off their hands. It is the reward of their own deeds, an exemplary punishment from God" (5:42). Only in Wahhabi Arabia is this stern legislation enforced. Moslem communities everywhere have adopted more liberal laws based on European practice. This is especially true of the modern Turks.

Local Institutions Adopted.—The tiny Medinese community of Mohammed's days ex-

panded until it encompassed first the entire Arabian peninsula, then the Fertile Crescent to the north, and later adjacent lands in North Africa, Southeastern Europe, Western Asia, and Central Asia. It soon became apparent that the laws worked out for it did not suffice to meet the multitudinous and varied problems, political and economic, which confronted the far-flung caliphal state and its component parts. To supply the deficiency it was only natural for the new Moslem state to adopt much of the governmental organization of the conquered lands, together with the necessary local laws and methods of procedure.

When the seat of the caliphate was transferred to Syria, the ruling Moslems retained the native Christian staff, remnant of the Byzantine system, who continued for some time to keep their records in Greek. The provincial system of administration and taxation, somewhat modified, was continued. When a new caliphate arose in Iraq, the Persian system of rule through vizirs and provincial governors was appropriated. The Ottoman caliphs inherited Byzantine institutions, and followed Byzantine political patterns. What in the long run determined the governmental theories and administrative structures of the many successive and contemporaneous Moslem governments in Asia, Africa, and Europe was not so much the Koran and the Sunnah as the fresh heritage and the force of events in the new locales.

New Devices.—Meantime Moslem legists were exercising their ingenuity to provide new devices for meeting the new situations. In all the conquered territories Arab governors found themselves confronted with problems which had no exact counterparts in the limited Arabian experiences. The administrators in some such cases had to resort to their personal judgment and sense of equity (*ra'y*). This, then, became a secondary source of legislation. Under other circumstances it was found that for certain new cases parallels could be discovered in early Islamic experience, and judged accordingly. Reasoning by analogy (*qiyās*), analogy to a decision recorded in the Koran or tradition, thus became another new source of authority. Gradually a third doctrine was worked out, that of the consensus of opinion (*ijmā'*). According to this doctrine, all such practices or articles of belief as are general among Moslems are an acceptable part of religion. To bolster the theory behind this doctrine, Mohammed was quoted as having said: "My community shall not agree on an error."

Four Rites.—On the basis of these sources, four permanent schools of jurisprudence arose in Islam. The earliest and most liberal among them was that established by abu-Hanifah, who flourished in Iraq, where he died in 767. The school named after him, Hanafite, which emphasizes the principle of analogical deduction, today predominates in Turkey, Western and Central Asia, and India. A contemporary of abu-Hanifah, Malik ibn-Anas (d. 795), labored in Medina; he was naturally more conservative than his Iraqi colleague. Malik stressed the importance of the consensus of opinion as prevalent in Medina, and his school struck root in North Africa and Spain. The third school of jurisprudence, the Shafi'ite, occupies a medial position between the liberal Hanafite rite and the conservative Malikite. It still dominates

ISLAMIC ART AND ARCHITECTURE

Lower Egypt, eastern Africa, Palestine and the East Indies. Al-Shafi'i, its founder, was born in Palestine but spent most of his life in Baghdad and Cairo, where he died in 820. His pupil, ibn-Hanbal of Baghdad (d. 855), insisted on uncompromising adherence to the Koran and tradition, and became the founder of the fourth and most conservative of the rites. The Hanbalite school declined after the 15th century but was revived by the Wahhabis, strict traditionalists, in the 18th. The ruling family of Saudi Arabia is Wahhabi.

All four schools are orthodox. The Shi'ites, however, utterly reject consensus of opinion as a source of legislation, and follow a rite of their own. They maintain the absolute authority and judgment of the infallible imam, successor of Ali. The Shi'ites, moreover, hold that their own spokesmen are qualified to interpret the ideas of their imams; the Sunnites, on the other hand, maintain that the "door of interpretation has been closed forever."

ISLAMIC ART AND ARCHITECTURE, *is-lām'ik*. The Arabs, who in the 7th century A.D. embarked on the conquest of the huge area stretching from Spain to India, brought very few, if any, important artistic or architectural ideas with them. It is in the earlier arts of Rome, Byzantium, Iran, and, more remotely, India, that one must look for most of the formal and technical sources of Islamic art and architecture. But the faith of Islam which created the major bond of unity between the very diverse peoples of the Muslim world did carry with it certain physical requirements and ideological precepts which affected the arts. Of these, three may be mentioned as of particular significance.

First, the practice of Islam required in every center of importance at least one place of worship (Arabic *masjid*, whence "mosque"), which was also—especially in early times—the main social and political center of the city. The typical mosque had to be large in order to hold most of the population of a city; in addition, within the first century after the appearance of Islam, the mosque acquired certain elements which were to become standard in all Muslim countries, even though their specific shape varied: the *mihrab*, or niche, on the back wall of the mosque, which originally symbolized the place from which Mohammed led prayers, and later came to indicate the position of Mecca toward which prayer is directed; the *mimbar* (*minbar*), a chair for the preacher and leader of prayers; one or several

Court and sanctuary of the Umayyad or Great Mosque, Damascus, Syria, built in the early 8th century.

minarets, towers from which the faithful are called to prayer; and a place for the ritual ablutions which precede prayers.

Second, one of the main tenets of Islam was its absolute monotheism, and in particular its conception of God as the only Creator. Since representations of living beings in ancient and medieval times often had the magic significance of equating or even replacing reality, Muslim theologians (and not, as is often thought, the Koran) maintained that representations of living beings were infringements on divine prerogatives. In fact it was only in religious art that this opposition to representations made itself felt;

Mosque of Omar (Dome of the Rock), city of Jerusalem, built by the Umayyad caliph Abd-al-Malik (r. 685-705).

George Palmer from Black Star

its main consequence was the development of a secular art at the expense of a religious one.

Third, the central source of the Muslim faith is the Koran, the sum of the revelations given by God to His Prophet. The holiness of the Koran and the divine nature of its message led the Muslim world to impart holiness to any written text, and as a result calligraphy became the most original and most complex artistic form in the Muslim world, even though the least accessible to untrained eyes.

MAJOR PERIODS OF ISLAMIC ART

Umayyad Period (661-750).—The Umayyad period was the formative one for Islamic art (see Umayyads). The center of the Umayyad Empire was in Syria and Palestine, where most of the monuments which remain from this time are found. The Great or Umayyad Mosque (begun in 705) in Damascus and the Dome of the Rock (691) in Jerusalem are the two major Umayyad religious buildings. In construction (the use of arches on columns and piers, and of domes) and decoration (mosaics) they follow the methods and uses of the earlier Christian civilization, but the plan and size of the Great Mosque of Damascus (a rectangular area 516 by 328 feet consisting of a courtyard surrounded by a portico on three sides and a three-aisled sanctuary on the side facing Mecca) and the purpose of the Dome of the Rock (to establish a Muslim holy place in the holy city of Christians and Jews, later considered as the place from which Mohammed ascended into heaven) show consideration for the physical requirements of the new civilization. In addition to these two edifices, there remain from this period a large number of princely residences, mostly scattered in the Syrian Desert: Mshatta (al-Mushatta), Khirbat al-Mafjar, Qasr al-Hayr, and Qusayr 'Amrah. These were decorated with frescoes representing the lives of the princes and with stucco sculptures, both representational and decorative. The style and the

iconography of these paintings show considerable influences from the Iranian East mixed with those of Byzantine art, reflecting thereby the whole extent of the newly conquered empire. In addition, architectural decoration (especially of the well-known Mshatta façade) exemplifies new techniques in ornament—the covering of the whole surface of the wall with intricate designs of flowers, leaves, fruits, and geometric motifs.

Period of the Caliphates (750-Mid-11th Century).—This period saw the formation of the great new Islamic metropolitan and cultural centers: Baghdad, founded in 762; Cairo, founded in 969; and Córdoba, an older city transformed by the Umayyads of Spain into the major urban center of Western Europe as early as the 8th century. Although the period is less fully documented by monuments than the preceding one, it is important both because of the individual styles which made their appearance then, and because it was remembered in later times as a particularly brilliant time. In architecture, the great ruined mosques of Samarra (on the Tigris, temporary capital of the Muslim world in the 9th century), the Azhar (972) and Hakim (990-c. 1013) mosques in Cairo, and especially the splendid mosque of Córdoba (begun in 786), show that Muslim architects had fully developed a new type of religious building. Using brick or stone, pillars or columns, long naves or square bays, flat roofs or vaults, they created large hypostyle halls which were preceded by porticoed courts. The orientation of the halls toward Mecca was often emphasized by a high central nave and by a dome in front of the mihrab. As a rule these mosques show a remarkable simplicity of design and construction, but in some cases, as in Córdoba, certain novelties appear. The arches are broken up into smaller units which in turn are arranged into patterns more decorative than structurally important, and similar effects are created in domes. This tendency to conceive of an architectural building as a decorative unit came to be characteristic of Islamic architecture and is further emphasized in Córdoba and elsewhere by the importance given to stucco and stone sculptures, decorative brick designs, and mosaic decorations on the most important parts of the buildings.

Since little has remained of secular building from this period, we do not know much about the architecture of the celebrated palaces which adorned Baghdad or Cairo; but objects in gold, silver, bronze, wood, silk, and ceramic, together with stucco fragments from Samarra, have given us a fair idea of the luxury which surrounded the princes who, like Harun al-Rashid, contributed to creating the *Thousand and One Nights* image we have of that period. The most important characteristic of many of these objects, and especially of the stuccoes from Iraq and the woods from Egypt, is the arabesque, a decorative design using geometric, vegetal, or purely abstract motifs so arranged that the design is always symmetrical, tends to cover the whole surface to be decorated, and can be continued indefinitely. In this type of ornament the central motif loses its individual meaning and becomes absorbed into a continuous surface design.

Among individual objects of this period the most remarkable ones are the bronzes of Fatimid Egypt; the ivories of Egypt, Spain, and Sicily; and the splendid series of ceramics from Egypt, Iraq, and eastern Persia. It was probably in Iraq that the greatest Islamic contribution to

the potter's art was invented, namely, luster—the covering of the object with a thin vitreous coat which gives it a brilliant and glowing effect after firing. The most novel designs, however, are found in eastern Persia. There, in the so-called Afrasiyab group, we see for the first time a very effective use of black or red inscriptions on a monochrome ground. There, also, in some of the types uncovered at Nishapur, we meet with more elaborate designs combining animal, human, and vegetal elements in a fantasy of strong colors and simplified shapes.

Seljuk Period (Mid-11th Century—Mid-13th Century).—In the 11th century the Seljuks, a dynasty of Ghuzz Turks, restored a semblance of order to a disintegrating caliphate (see SELJUKS). Seljuks ruled the caliphate more or less directly for about a century after having taken Baghdad in 1055, and their ideas influenced the whole of the Near East. Even in Egypt and the

West, where Seljuk rule was not fully accepted, we find artistic and intellectual developments closely related to the Seljuk developments proper. It was a period of great fermentation in the Islamic world: while the Turkish conquests of Anatolia and parts of India and the conversion to Islam of much of Central Asia widened the area of the Islamic world, the newly developed feudal structure gave power and wealth to dozens of centers which previously had been mere provincial towns. It was also during this period that Persia took over to a large extent the cultural leadership of the Muslim Near East and the great Persian lyrical and mystic poetry was developed.

In architecture two major novelties are to be noted. The first one is in the rapid development and spread of a Persian brick architecture. There appeared a new plan for mosques, exemplified in the Congregation Mosque or Masjid-i-Jami of Isfahan, which consisted of four monumental *iwān*'s opening on a central courtyard, with the direction of Mecca emphasized by a large dome at the rear of one of the *iwān*'s. (An *iwān* or *ivan* is a vaulted hall of pre-Islamic origin closed on three sides and entirely open to the outside on the fourth.) The monumental *iwān*'s are separated from each other by complex vaults on heavy pillars, with a façade made up of two tiers of arches which repeat on a reduced scale the generally keel-shaped pattern of the central *iwān*. The main emphasis of the builders was on the vaults and domes; and with the traditional inventiveness of Muslim builders for decorative designs, they developed splendid zones of transition between square and dome. The main feature of these transitional zones was the *muqarnas* (also called stalactite or honeycomb), consisting of sections of niches and vaults arranged in a three-dimensional symmetrical order. Also in the Seljuk period glazed tiles began to be used for the decoration of façades of mosques and certain parts of the interior.

The second architectural novelty of the Seljuk period is the reappearance and rapid expansion of mausoleums, often attached to pious foundations such as mosques, hospitals, and schools. The exact origins and historical significance of these mausoleums still await investigation, but with their characteristic domical shapes, large and heavily decorated or simple and unadorned, they have formed a characteristic feature of the Islamic landscape since the time of the Seljuks.

In metalwork and ceramics this was also a time of considerable change. Newly adopted or newly refined techniques (including silver inlay on bronze and better methods of fixing colors on ceramics) provided the Seljuk artist with excellent means to develop new artistic motifs. In metalwork, originally utilitarian objects such as candlesticks, kettles, trays, and boxes were adorned with images depicting incidents from the lives of princes and with complex arabesques of geometric and vegetal forms, and were thus transformed into splendid works of art in which great craftsmanship was combined with endless variations on a few established themes. In ceramics, the Seljuk period was the heyday of Persian potters. In centers such as Rayy and Kashan, complex compositions and at times brilliant colors were combined with iconographic themes derived from stories, lives of princes, and mystical poems, to create bowls, plates, and tiles in which the

ISLAMIC ART AND ARCHITECTURE

decorative spirit of Persian art found its full expression.

Also in this period we see the growth of illustrated manuscripts. The most characteristic among them were the illustrations of literary works, such as the amusing stories of al-Hariri's *Maqamat* (see HARIRI, AL-). Within certain stylized limitations, such as a tendency toward a two-dimensional vision of the image, these miniatures are splendid documents of the life of 12th and 13th century Arab towns; in an interesting opposition to most of the earlier and contemporary traditions, the miniaturists consciously attempted to copy scenes and activities which they themselves had witnessed.

LATER ISLAMIC ART

The Mongol conquest, culminating in the sack of Baghdad in 1258, profoundly changed the complexion of the Muslim world. There emerged four separate Muslim worlds whose relationship to each other decreased with time and whose arts, although occasionally still international in character, tended to develop separately.

Arab World.—From 1258 to 1517 the main power in the Arab world was Egypt under the dynasty of the Mamluks (see MAMELUKES). As rulers these former slaves covered the cities of Egypt and Syria (especially Cairo) with a splendid series of monuments, mostly religious foundations, which testified less to their piety than to their great wealth. Few new forms were created; the iwans of Persian origin, the traditional porticoed courts, and the domes of the previous period predominated, but in the quality of the workmanship, and in the splendor of the decorative effects in marble, stone, mosaics, glass, and stucco, the Mamluk monuments of Cairo are quite unique. These include the complex of Qalaun (Qalawun) (1284) and the mosques of Barquq (1386), Sultan Hasan (1362/1363), and Baybars (1269), to name but a few. In other techniques, especially metalwork, glasswork, and miniature painting, the results were not less effective, at least in technical virtuosity; but here again the liveliness and inventiveness of the preceding centuries made way for a somewhat dry perfection.

In the West, the Muslim kingdoms of North Africa and Spain were politically unstable, but in the Alhambra of Granada (constructed in the 13th and 14th centuries) they left one of the few remaining examples of a late Islamic palace. The Alhambra's luxurious gardens, fountains, and wealth of decoration, were a constant source of inspiration to the West, and its themes were often copied by Christian princes.

Persian World.—Of all the areas which suffered from the Mongol conquest, Persia revived soonest and, in the four centuries which followed the conquest, soared to the greatest heights. While its architecture—notably the Blue Mosque in Tabriz, completed in 1465; the Royal Mosque (Masjid-i-Shah) at Isfahan, completed in 1616; and the mausoleums built at Samarkand at the time of Tamerlane—was as splendid as ever, and while its decorative arts (especially carpet weaving) acquired at that time a fully justified renown, the greatest and most characteristic art of post-Mongol Persia was its miniature painting.

The origins of this Persian painting are to be found in earlier Islamic art, in China, and in Central Asia, but its spirit reflected the themes and motifs, as well as the ideals, of Per-

Illustration Research Service

Tilla-kari Madrasah, Samarkand, USSR, 17th century.

sian poetry. Without attempting to give a chronology of its major phases, it is possible to distinguish in it four major moods. In the first, or heroic, mood the illustration of Firdausi's great Persian epic, *Shah Nameh* (q.v.), provided occasions to depict the brilliant feats of princes and heroes of Persian antiquity, and to convey, through a mixture of artificial backgrounds and precision of detail, something of the legendary and yet deeply living character of the work. An excellent example of this style is provided by the manuscript known as the Demotte *Shah Nameh*, the separate leaves of which are now scattered throughout the world. The second, or lyrical, mood chose its themes from love stories and mystical poems. In it were developed motifs of permanently blooming gardens in which young and handsome princes held court or lovers met at night, and of brilliantly static throne scenes. A world of fantasy was created in which precision and inventiveness of detail were prized rather than originality of composition or of subject matter. A third mood is exemplified by Behzad (Bihzad, late 15th century), one of the earliest identifiable personalities of Persian art. Although there is much disagreement about what works should be attributed to him, one characteristic of his work was the introduction of realistic details, often taken from direct observation of men, into the formal stylized world of Persian painting. The fourth type of painting did not begin until the late 15th century and flourished mostly in the two following centuries. It consists chiefly of portraits of courtly personages, done in the same precise technique as the book illustrations, but often with a firm and subtle irony in the representation of the princes and princesses

of Iran. An interesting development of this later form was the introduction of more popular scenes: shepherds, washing women, and other subjects not usually found in earlier painting.

Although these four moods appeared chronologically in the approximate order in which they have been enumerated, the later moods were developed in addition to, rather than in place of, the earlier ones. In the art of the Safavid dynasty (1502-1736) they all appear in a perfection of color and design rarely achieved before.

Ottoman World.—In Anatolia and the Balkans power was in the hands of the Ottoman Turks, who conquered Constantinople (modern Istanbul) in 1453. Ottoman art derived from Byzantine, Seljuk, and Persian sources. The most characteristic mosques took over the ancient plan of Hagia Sophia (Saint Sophia) in Constantinople and transformed it into logically conceived and structurally perfect monuments, whose high domes flanked by slender minarets and adjoining courtyards with domed porticoes make up the magnificent skylines of Istanbul and other Turkish cities. Its style of painting was derived from Persian miniatures, but in its fascination with historical events and its greater realism in the representation of the background, it later moved away from its early models. While rarely attaining the formal perfection of Persian art, Ottoman art provides a running commentary on a brilliant history. In addition to its painting and architecture, Turkey had illustrious schools of ceramics and carpentry.

World of Muslim India.—The first large-scale Muslim penetration of India occurred in the 11th century, and a number of monuments show the amalgamation of Near Eastern and Indian motifs which began to take place at that time. However,

it is from the 15th century onward, when Persian artists were attracted to the Muslim courts in India, that India's greatest Islamic art was created. Its major characteristic is its highly successful blending of Persian and Indian traditions. In architecture, this can be seen in the celebrated mausoleum at Agra known as the Taj Mahal (q.v.; 1632-1653) whose harmonious perfection and ideal setting make it one of the world's great monuments. It is mostly in miniatures, however, that we see the Persian traditions of courtly, epic, and portrait painting infiltrated by a different spirit, whose greater interest in spatial representations, greater fascination with atmosphere and the transparency of textiles, and greater concern with individual actions led to an entirely new art. In its full realization this new spirit belongs to the tradition of Indian art rather than to Islamic art proper.

AESTHETIC VALUES OF ISLAMIC ART

While it is impossible in a brief survey to present every facet of an art which extended for 10 centuries from Spain to India, an appreciation of Islamic art requires the realization of two major facts. First, most Muslim art was created for the aristocratic taste of the courts; its miniatures reflected the idealized life of which Persian princes dreamed, and the artificial world whose changeless beauty the secular patrons of the arts sought to reproduce in the palaces. Even the great mosques are, in the final analysis, inspired less by the faith than by the glory of the princes who sponsored their construction, and it is mostly in the small sanctuaries and mausoleums that the depth and intensity of Muslim religion is evident. As a secular art, however, emphasizing luxurious life and a luxurious setting for life, Islamic art has had no equal: thus can be explained its tremendous impact on the art and on the way of life of Christian princes in the Middle Ages and later.

Second, Islamic art is essentially an art of artisans. Except in its later phases, when certain outstanding individuals appear among architects and painters, it was an art whose creators were more often fascinated by the technical possibilities of their media than by ideologies or by purely formal considerations. They vied with each other in inventing new subtleties in their use of standard iconographic motifs; and it is from this endless virtuosity of their creations, from their inventiveness in small details, and from the striking combinations of forms and themes of different origins that the greatness of Islamic art derives. Although Muslim artists achieved a powerful monumentality in such buildings as the mosques of Isfahan, Córdoba, and Istanbul, even in these buildings decorative values and the understanding of architecture as a means to enchant rather than as a means to impress have often given to the largest and most monumental Islamic creations a character of intimacy and of decorative excellence which has overshadowed their monumentality proper.

Other features of the intellectual, social, and historical development of the Muslim world have left their imprint on Islam's artistic production, but it is in these two that Islamic art finds at the same time its greatness and its limitations.

ISLAMIC LITERATURE. Islamic literature may be defined as comprising the books of a religious character written by Muslims in the languages of Islam. This literature sprang out of the Koran (q.v.); the life, acts, and sayings of the prophet Mohammed (c. 571-632); and the religious experiences of his followers. Composed in both prose and verse, it has exercised a profound influence upon the secular writings of the Muslim peoples.

The Koran.—The primary religious document of Islam is the Koran, believed by Muslims to comprise the divine revelations received by Mohammed over a period of many years through the mediation of the archangel Gabriel, and collected by Mohammed's disciples shortly after his death from "scraps of parchment and leather, tablets of stone, ribs of palm branches, camels' shoulder blades and ribs, pieces of boards, and the breasts of men." The authorized text, with its division into 114 chapters (suras) of varying length and content, was established by order of the third caliph, Othman (r. 644-656). The Koran is composed in rhythmical and rhyming prose, held to be of miraculous and inimitable excellence. The interpretation of the Koran gave rise to a very extensive exegetic literature, and a very great number of commentaries—some extremely voluminous—have been produced from the early years of Islam down to the present day. The most esteemed are those written by the historian al-Tabari (838-923), which has been printed in 30 folio volumes, the grammarian al-Zamakhshari (1074?-1143), the philosopher Fakhr al-Din al-Razi (1149-1209), and the theologian al-Baidawi (d. ?1286). In modern times important commentaries have been written by the Egyptians, Muhammad Abduh (1849-1905) and Muhammad Rashid Rida (1865-1935) and the Indians, Sir Sayyid Ahmad Khan (1817-1898) and Abul Kalam Azad (1888-1958), among others.

Hadith.—The fundamental authority in questions touching the theology, ritual, and law of Islam is the Koran. However, the Koran was soon found to be far from providing the solutions for all problems arising out of the rapid spread of the faith, and the practice of the Prophet was looked to for filling the gaps. Details of his daily

life and casual sayings were eagerly preserved and transmitted, and out of this miscellaneous material the body of traditions known as the Hadith grew rapidly. Handed down orally for several generations by men scattered through the four quarters of the Muslim world, these traditions became exceedingly numerous and covered a great multitude of topics. From quite early times learned or pious individuals made collections of Hadith, but it was not until the rise of the law schools that the need was felt to arrange and codify, and to some extent to verify, the heterogeneous accumulations. The first *Musnad* or assemblage of testified traditions is assigned to abu-Hanifah (abu-Hanifa, 699-767), founder of the Hanafi law school. His initiative was soon followed by Malik ibn-Anas (715?-795), father of the Maliki school, whose compilation called *al-Muwatta'* (*The Leveled Path*) is the fundamental textbook of his school and has attracted many commentators. His disciple, al-Shafi'i (767-820) established a third codification, while Ahmad ibn-Hanbal (780-855) made a fourth, considerably larger than the preceding three. These last two works are the foundation documents of the Shafi'ite and Hanbalite schools of jurisprudence respectively.

The four founders of these law schools, and their colleagues of the Shi'ite persuasion and the lesser sects, were concerned to promulgate and arrange those traditions which had to do with the theory and practice of Islamic law. But countless Hadith unrelated to law were also in circulation, and in the 9th century six outstanding scholars worked to establish a canon of authentic traditions. First and most famous was the Persian, al-Bukhari (810-870), who is said to have sifted through several hundreds of thousands of traditions in the course of giving his approval to a mere 2,762. His contemporary, Muslim ibn al-Hajjaj of Nishapur (d. 875) compiled a similar collection, called, like that of al-Bukhari, *al-Sahih* (*The Genuine*), which is esteemed as second in authenticity only to al-Bukhari's work. The next generation produced supplementary compilations by abu-Dawud (817-889), al-Tirmidhi (d. about 892), ibn-Maja (d. 886), and al-Nasa'i (d. 915). These famous texts have provided Muslim scholars through all the succeeding centuries with plentiful material for comparison and commentary. Indeed, a high proportion of the extensive religious literature of Islam is devoted to exegesis of the Koran and commentary on the Hadith.

Biographies of Mohammed.—The biography of Mohammed engaged the attention of many writers who used similar traditional material to reconstruct the life of the founder of their faith. The first biography of the Prophet is that written by ibn-Ishaq (d. about 768), a recension of which was incorporated by ibn-Hisham (d. 834) into his own *Sira* (Biography). The historians al-Waqidi (747-823) and ibn-Sa'd (d. 845) devoted much care to the life of Mohammed, and their accounts were important sources for later chronologists such as al-Baladhuri (d. about 892), al-Tabari (838-923), and ibn-al-Athir (1160-1234). Derivative biographies of an increasingly hagiological character were written in Persian and Turkish, and the life of the Prophet has attracted a number of contemporary writers.

Theology.—Orthodoxy.—The spread of Islam soon led to a battle of sects and schisms, out of which the science of theology eventually de-

veloped. The foundations of orthodoxy were finally laid securely by al-Ash'ari (873/874-935/936), the father of Muslim scholasticism. Important works on comparative religion, in which Christian and Jewish as well as Islamic sects were discussed, came from the pens of ibn-Hazm of Córdoba (994-1064) and the Persian al-Shahrastani (d. 1153). Meanwhile, philosophy, stimulated by the translation into Arabic of the works of Plato, Aristotle, and their late Hellenistic commentators, had been pursuing a comparatively independent path with al-Kindi (d. about 870), al-Farabi (870?-950) and ibn-Sina (Avicenna, 980-1037), all of whom had paid at least lip service to Islam. In the 11th century, however, philosophy collided violently with theology, and al-Ghazzali (1058-1111), an eminent jurisconsult as well as theologian and mystic, wrote the *Tahafut al-Falasifa* (*Incoherence of the Philosophers*) to "demolish" the constructions of the Islamic philosophers. He was answered from Morocco by ibn-Rushd (Averroës, 1126-1198) in his *Tahafut al-Tahafut* (*The Incoherence of the Incoherence*), but his reply was little heeded and theology prevailed, the more so when the Syrian, Ahmad ibn-Taymiyah (1263-1328), renewed the onslaught and silenced the philosophers for centuries to come.

Sufism.—A middle way between rationalism and dogma was discovered by the Sufis, the mystics of Islam. Their ascetic mode of life, allegedly modeled on that of Mohammed, brought them ecstatic experiences out of which they developed a theory of the "path to union with the Divine." Sufism soon produced an abundant literature in both prose and verse. Lives of the saints were written in all the languages of Islam, notably by al-Sulami (d. 1021), abu-Nu'aim al-Isbahani (d. 1038), and al-Sha'rani (1493-1565), in Arabic; and by the mystical poets, Farid al-Din 'Attar (d. about 1220) and Jami (1414-1492), in Persian. There also exist many biographies of individual mystics and of members of the dervish confraternities. The discipline and doctrines of Sufism were established primarily by writers such as al-Muhasibi (d. 857), al-Junaid (d. 910), al-Hallaj (858-922), and al-Tirmidhi (fl. 900); they were further developed and systematized by al-Sarraj (d. 988), abu-Talib al-Makki (d. 996), al-Kalabadhi (d. about 1000), al-Qushairi (986-1072), and the Persian, Hujwiri (d. about 1075). The reconciliation between orthodox theology and Sufi doctrine was worked out by al-Ghazzali in a number of works, above all in the *Ihya'* (*Revivification*) and the *Kimiya-yi Sa'adat* (*Alchemy of Happiness*, a Persian digest of the *Ihya'*).

After al-Ghazzali very many Sufi works were written; it is possible only to mention the leading authors. Abu Isma'il al-Ansari (1005-1088) wrote devotional works in Arabic and highly esteemed prayers in Persian. Muhi al-Din al-Jilani (1078-1167) wrote many books, including sermons and prayers. Shihab al-Din al-Suhrawardi al-Maqtul (executed for blasphemy in 1191 at the age of about 37), attempted to reconcile philosophy and mysticism; in addition to numerous learned Arabic treatises he composed mystical allegories in Persian. His namesake, Shihab al-Din al-Suhrawardi of Baghdad (d. 1234), founded the Suhrawardi order of dervishes. Muhi al-Din ibn-'Arabi (1165-1240), who was born at Murcia and died in Damascus, wrote well over two hundred books expounding his deep and original theosophy, as well as much mystical poetry; his main works are the *Fusus al-Hikam* (*Bezels of*

Wisdom) and *al-Futuhat al-Makkiya* (*Meccan Revelations*). The theme of divine love (the lover and the beloved) was treated in a series of delicately expressed Persian treatises by Ahmad al-Ghazzali (d. 1126), Fakhr al-Din 'Iraqi (d. about 1290), and Jami. Sufi works of various kinds abound also in Turkish, Pashto, Urdu, and Malay. Among the later writers the most original and voluminous was the Egyptian, al-Sha'rani (d. 1565), who among other things composed his autobiography.

Religious Poetry.—Religious poetry, much of a very high order, abounds in the languages of Islam. During Mohammed's lifetime devotional poems were written in defense of the new religion, and panegyrics composed in honor of its founder; the most famous of these was the work of Ka'b ibn-Zuhair. This celebrated paean is exceeded in popularity only by the *Burdah* (*Cloak*) of the Egyptian al-Busiri (1213-c. 1296), commemorating a miraculous cure from paralysis following a vision of Mohammed; the poem itself was afterwards believed to possess magical qualities, and it has been repeatedly calligraphed and imitated. Most Persian epics begin with long sequences on the unity of God and the virtues of His Prophet. The life and miracles of Mohammed inspired the Turkish poet, Sulaiman Chelebi (d. 1421), to write his *Mevlidi Sherif* (*Nativity Ode*) which is still recited on certain religious festivals. Religious and ascetic themes dominate the poetry of abu 'l-'Atahiya (748-826). Most of the Arab mystics wrote verses of a metaphysical or ecstatic kind; the greatest among them being the Egyptian ibn-al-Farid (1181-1235), whose longest composition, the *Nazm-al-Suluk* (*Poem of the Way*), runs to 760 couplets all rhyming on the same letter.

Poetry in Persian is largely religious and mystical in character. To the national poet, Firdausi (c. 940-c. 1020), is attributed an epic on the story of Joseph and Potiphar's wife, based upon sura 12 of the Koran; and the same subject was afterwards treated by numerous Persian and Turkish poets, among them Jami, who gave it a mystical turn. The Ismaili propagandist, Nasir-i Khusrau (1003-1061), composed many fine religious poems. Sana'i (fl. 1131) wrote a long epic on the mystical life with illustrative anecdotes, as well as a kind of *Pilgrim's Progress*. Farid al-Din 'Attar composed many long mystical poems, some in the form of allegories; the best known of these is his *Mantiq al-Tair* (*Speech of the Birds*), of which a greatly abridged paraphrase was made by Edward FitzGerald, the translator of Omar Khayyám. Beyond dispute the finest mystical poet of Islam, and perhaps of the world, was Jalal al-Din Rumi (1207-1273), founder of the Mawlawi (Mevlevi) order of whirling dervishes. His *Mathnawi*, in about 25,000 couplets, ranges widely over the mystical life and experience, and is far superior to Sana'i's earlier work; a complete English translation was made by Reynold A. Nicholson. Rumi also composed over two thousand odes, many of considerable length and all of a mystical character, said to have been dictated in a state of trance. His biography was written in verse by his son, Sultan Walad.

Mystical quatrains have been composed by many poets, including abu-Sa'id ibn Abi 'l-Khair (967-1049); the wandering dervish, Baba Tahir (fl. 1030), who wrote in Persian dialect; Farid al-Din 'Attar; and Rumi. Fine

mystical lyrics were written by 'Iraqi, Baba Kuhi (d. 1050), Ibn Yamin (1286-1367), Qasim al-Anwar (1356-1433), and many others; mystical ideas also permeate the poetry of Sa'di (1184?-1292) and Hafiz (c. 1326-1389). The last great Persian mystical poet was Jami, who wrote several religious epics, including the *Salaman u Absal* which FitzGerald put into English.

Of the many poets who composed on mystical topics in the Turkish language, the best esteemed is the 14th century writer, Yunus Emre (d. 1320?); others include Gulshehri (14th century) 'Ashiq Pasha (1272-1337), Nesimi (executed in 1404), and Fuzuli (1494-1555).

In modern times little religious poetry of importance has been written in Islam. An interesting exception is Muhammad Iqbal (1876-1938) of Lahore, in present West Pakistan. Following in the footsteps of reformers like Sir Sayyid Ahmad Khan and Muhammad 'Abduh, he used the medium of Persian verse to disseminate his philosophical and political ideas of a revitalized and reunited faith.

ARTHUR J. ARBERRY,
Sir Thomas Adams's Professor of Arabic, University of Cambridge.

ISLAND, i'länd, a body of land entirely surrounded by water. Islands are usually classified as continental or oceanic. Continental islands rise from an underwater shelf extending from the mainland, and so have rock structure, fauna, and flora similar to that of the mainland. They are formed in several ways. When coastal lands are submerged by subsidence of the land or raising of the sea level, high points protruding above the encroaching ocean become islands. The British Isles, for example, were once a part of continental Europe, and many of the islands off the coasts of Scandinavia and northern North America were formed by submergence. Earth movements may separate a body of land from the mainland, as in the case of Madagascar, which was cut off from continental Africa by the sinking of a long, narrow strip of land called a rift valley. Wave action often wears away weak rock formations along the seacoast, so that the more resistant rocks become islands. The Isles of Shoals off the coast of New Hampshire are the result of such erosion. Ocean currents sometimes build up new islands by depositing sand and other debris offshore. Fire Island, off Long Island, New York, was formed in this way.

Oceanic islands are usually surrounded by deep water, far distant from continental shores; they are generally volcanic or coralline in structure and have a limited flora and fauna. The Hawaiian

Islands, Samoa, Fiji, and other large islands of the central Pacific were built up from the ocean floor by volcanic action until they rose above sea level. Mauna Kea on the island of Hawaii rises nearly 32,000 feet from the floor of the sea, making it the highest mountain in the world. The coral atolls characteristic of the islands of Micronesia in the western Pacific were formed by coral growth along the fringe of subsiding volcanic islands until the original islands had become completely submerged and only the coral rings remained. (See also CORAL AND CORAL REEFS.)

Australia is sometimes called the world's largest island, but it is usually classed as a continent, with its own continental shelf and associated islands such as New Guinea. Greenland is generally regarded as the largest true island.

ISLAND NUMBER 10, The Siege of, the first Civil War engagement in the campaign of the Union forces to divide the Confederacy by seizing control of the Mississippi River. After the capture of Fort Donelson (q.v.) on Feb. 16, 1862, the Union fleet of gunboats and mortar boats, commanded by Flag Officer Andrew H. Foote, steamed down the Mississippi to assist Maj. Gen. John Pope in taking Island Number 10. Situated in a bend of the river in northwestern Tennessee, the island was protected by 49 guns and 12,000 men, including those on the opposite Tennessee shore, and by a nine-gun floating battery. On the night of April 6, four of Pope's river transports bypassed the Confederate position by way of a shallow channel cut through the swamps in the bend adjacent to the island. The deciding factor in the siege, however, was the action of the Union gunboats *Carondelet* and *Pittsburgh*, which passed the Confederate batteries at night and provided a covering fire while Pope's troops crossed the Mississippi below Island Number 10, captured the Confederates' mainland positions, and seized the only route of escape from the island. On April 7, 1862, Island Number 10 surrendered, with a loss to the Confederates of over 5,000 men captured and large quantities of arms and equipment. The island no longer exists, having been washed away by river action after the Civil War.

ISLAY, i'lā, island, Scotland, the most southerly of the Inner Hebrides off the west coast of Argyll, Scotland. Islay is about 14 miles west of Kintyre Peninsula and lies southwest of Jura, from which it is separated by the Sound of Islay. With an area of nearly 234 square miles, the island is hilly in the east, rolling or level in the west. The chief town is Port Ellen, which is a noted golfing resort. The industries of the island include fishing, farming, whiskey distilling, and quarrying. Islay was formerly the seat of the Lords of the Isles (Macdonald clan). Pop. (1951) 4,267.

ISLE LA MOTTE, il'lä möt', island, Vermont, in the northern part of Lake Champlain, about 10 miles south of the Canadian border. The island is six miles long and two miles wide. It was discovered by Samuel de Champlain in July 1609, and was named after a French officer, Captain Sieur de la Motte, who about 1665 erected a small wooden fort, called Fort Ste. Anne, on the south shore for protection against Mohawks. On Aug. 8, 1776, Benedict Arnold, after engaging the Indians in the British service on August 6,

at the Bouquet River, fell back to Isle La Motte, where his fleet remained anchored until August 19, when he sailed south toward Cumberland Head. Isle La Motte was settled in 1785 by Ebenezer Hyde, Enoch Hall, and William Blanchard, and was organized as a town in 1790. The quarries of black marble on the island are the oldest in the United States.

ISLE OF MAN, Great Britain, an island in the Irish Sea, 16 miles south of Burrow Head, Wigtownshire, 221 square miles in area. It is 33 miles in length, and 12 miles in breadth at the widest point. A range of mountains crosses the island from northeast to southwest, culminating in Snaefell, 2,034 feet in height. The coast is rugged and precipitous in the southwest. Granite, red sandstone, limestone, and slate are quarried for building purposes. The air is dry, clear, and bracing, and much southern vegetation grows freely here, owing to the warm currents of the Gulf Stream which envelop the shores. Agriculture is the main industry. There are also woollen mills where the famous "Manx homespun" is made; and woollen knitted goods are produced. Ruins of ancient churches and chapels, castles, and fortresses dating from the 5th century are found throughout the island. Manx, the branch of Celtic formerly spoken by the people, is no longer in general use. The Isle of Man was subject to Scandinavian rulers from the 9th century until 1266, when it was ceded to Scotland. In 1399 it came into possession of the English crown. The legislature (Tynwald) consists of a Legislative Council and the House of Keys. The Council is composed of the lieutenant governor of the island, the bishop of Sodor and Man, 2 deemsters (judges), the attorney general, and 6 nominated members, of whom 2 are nominated by the lieutenant governor and 4 by the House of Keys; this latter body has 24 elected members. Douglas is the capital of the Isle of Man; and Castletown, Peel, and Ramsey are ports. Pop. (1951) 55,213.

ISLE OF PINES (Span. ISLA DE PINOS, ēz'la thā pē'nōs), a small island belonging to Cuba, 35 miles southeast of Pinar del Rio, 1,180 square miles in area. Nueva Gerona, the capital, is on the north coast. It is, in effect, two islands connected by a marsh, the one on the north being somewhat broken by hills and that on the south being low, flat, and sandy. The climate is healthful, and the fertile soil produces citrus fruits, pineapples, and potatoes. Mineral resources are extensive. Large marble quarries are worked. Cattle raising is the chief occupation of the people. For administrative purposes the island is a municipal district of the province of Havana. The island was discovered by Columbus in 1494. The United States Supreme Court ruled in 1907 that the island was not United States territory; this was ratified by the United States Senate in 1925, thus recognizing that the Isle of Pines was part of Cuba. Pop. (1953) 10,105.

ISLE OF WIGHT, wit, England, off the south coast, separated from Hampshire by the Solent and the Spithead. It is 23 miles from east to west, and 13 miles from north to south, the area being 147 square miles. The island, the ancient Vectis, is rich in antiquities, having

been inhabited in turn by the Romans, the Jutes, and the Danes. Cowes, the chief port, is the yachting center of England. Agriculture and fishing are of importance, and the island is a popular vacation resort. Pop. (1951) 95,594.

ISLE ROYALE, il' roi'āl (Fr. ēl' rwā-yāl'), an island in Lake Superior, southeast of Port Royal, Canada, part of the State of Michigan. It is 44 miles long and 8 miles wide, and has an area of 229 square miles. Prehistoric copper mines have been found. In 1940 the island was dedicated as a national park.

ISLES OF SHOALS, New Hampshire, a group of eight barren islands in the Atlantic Ocean, 10 miles southeast of Portsmouth, N. H., from which a daily steamer plies during the summer months. The three principal islands are Appledore (400 acres); Star (150 acres) and White (55 acres).

ISLES OF THE BLEST, or FORTUNATE ISLANDS, according to Greek mythology and legend an island group on the edge of the western ocean, where dwelt those fortunate beings on whom the gods bestowed immortality. Hesiod mentions the group, as do later authors. It is supposed that the idea of this paradise on an island group is due to the remembrance of an unrecorded voyage to Madeira and the Canary Islands, these being called Fortunate Islands in some medieval maps.

ISLETA, ēs-lā'tā, N. Mex., Indian pueblo in Bernalillo County, on the Rio Grande 10 miles south of Albuquerque, served by the Santa Fe Railroad. It is in the Isleta Reservation. Pop. 756.

ISLINGTON, iz'ling-tōn, England, a metropolitan borough of London, 2 miles north of Saint Paul's. Within it are the Royal Agricultural Hall, Pentonville and Holloway prisons, and several hospitals and educational institutions. Pop. (1945) 195,770; (1951) 235,645.

ISLIP, i'slip, town, New York, in Suffolk County, Long Island, on the shore of Great South Bay; it is served by the Long Island Railroad. Oyster fishing and agriculture are of importance, and the town is a popular summer resort. In the vicinity is a state hospital for the insane. The town is named for Islip, Oxfordshire, whence came the first English settlers in the 17th century. Villages within the town include Islip, East Islip, Central Islip, Sayville, Bay Shore. Pop. 172,959.

ISMAIL, is-mā'el (Arab ISMĀ'ĪL), Arab religious leader: d. 760. He was the eldest son of Jafar al-Sadiq, sixth imam (q.v.) of the Shi'ite Muslims, and was originally chosen by his father to succeed to the imamate. When Jafar was told that Ismail drank wine, however, he altered his choice in favor of his second son, Mūsa al-Kāzim. The majority of the Shi'ite sect accepted the change, but others, claiming Ismail was infallible, adhered to him as the seventh imam, though he died five years before his father. His followers, known as Ismailites (q.v.) or Seveners (adherents of the seventh imam), continue to number in the millions in Islam in the 20th century.

ISMAIL I, is-mâ-êl', shah of Persia, founder of the Safavid (Safawid) dynasty: d. Ardebil, Iran, 1524. He was a descendant of Sheikh Şafî-al-Dîn (1252-1334), a holy man of the Shi'ite Muslims, and named his dynasty after Şafî, who claimed descent from the seventh imam and hence from Ali, Mohammed's son-in-law. In 1502, Ismail assumed the title of shah and succeeded in establishing an independent national government, the first since the Arab conquest of Persia in the 7th century. His capital was at Tabriz in Azerbaijan, of which province he was a native. He made Shi'ism the state religion, and during the first 12 years of his reign added considerably to his dominions, conquering Baghdad, Iraq, in 1508 and overwhelming the Uzbeks in Khurasan in 1510. In August 1514, however, he was beaten at Chaldiran by the Ottoman Turks under Selim I, losing his capital temporarily to the invaders. He was succeeded by his son Tahmasp I, Ismail II (r. 1576-1577) was his grandson. See also PERSIA-IRAN—9. *History* (Safavids).

ISMAIL PASHA, is-mâ-êl pá-shâ, khedive of Egypt: b. Cairo, Egypt, Dec. 31, 1830; d. near Constantinople (now Istanbul), Turkey, March 2, 1895. He was the son of Ibrahim Pasha (q.v.) and nephew of Said Pasha (q.v.), whom he succeeded as Turkish viceroy in Egypt in 1863. By increasing the Egyptian tribute to Turkey, Ismail won from the sultan the right of succession from father to son in the vicerealty of Egypt, and was given the title of Khedive (1866). Determined, like his grandfather Mohammed (Mehemet) Ali, to modernize the country, he launched an ambitious program of public works and cultural improvements, including schools for girls, a national library, and a national geographic society; during his reign the Suez Canal was completed (1869) and Egyptian rule was extended to southern Sudan and along the Red Sea coast. To finance his projects, Ismail borrowed heavily from foreign sources, especially English and French; and when his credit was exhausted, he sold Egypt's share (over 40 per cent) in the Suez Canal Company for about £4 million. To guarantee repayment of the loans Ismail had made, Great Britain and France took control of Egypt's finances in 1876 and placed their own ministers in the government. When Ismail attempted to withdraw these concessions, the two powers persuaded the Turkish sultan to remove him (June 1879) as khedive in favor of his son Mohammed Tewfik Pasha (q.v.).

ISMAIL PASHA, Hungarian-Turkish general. See KMETY, GYÖRGY.

ISMAILIA, iz-mâ-i-lê-â, town, Egypt, on Lake Timsah, the central station on the Suez Canal, 45 miles northwest of Suez and 93 miles northeast of Cairo by rail. Founded in 1863, it was built as construction headquarters for the canal and named after Ismail Pasha. It has docking facilities, warehouses, and factories producing confectioneries and electric light bulbs. It is connected with Cairo also by the Ismailia Canal, built to provide water to villages along the Suez Canal and now used mainly for irrigation purposes, although it is navigable. Pop. (1947) 53,594; with suburbs, 68,338.

ISMAILITES, is'mâ-i-lîts (also ISMAILIAUS; Arab. sing. ISMÂ'ILÎ), a Shi'ite Muslim

sect, also called Seveners because they revere Ismail (q.v.) as the seventh, greatest, and last imam in the true lineage of Mohammed, and believe that he will come again. The Neo-Isma'ilites, a militant terrorist group which originated in northern Iran about 1090 and spread to Syria, became known as the Assassins (q.v.). The Isma'ilites proper number today about 20 million. Aga Khan IV, previously Prince Karim, became their spiritual leader and 49th imam on the death of his grandfather, Aga Khan III (q.v.) in 1957.

ISMAY OF WORMINGTON, iz'mâ, wûrm'ing-tûn, 1ST BARON (HASTINGS LIONEL ISMAY), British general: b. Naini Tal, India, June 21, 1887. The younger son of Sir Stanley Ismay, he attended the Royal Military College at Sandhurst, was commissioned in the British Army in 1905, and between 1914 and 1920 fought in Somaliland, East Africa, where he led a camel corps column in 1920 against the "Mad Mullah," Mohammed ibn-Abdullah. He fulfilled assignments in India during the next few years and in the early 1930's, and served in London with the Committee of Imperial Defence as assistant secretary (1926-1930), deputy secretary (1936-1938), and secretary (1938).

At the outbreak of World War II, Ismay was appointed (1940) deputy secretary for the military to the war cabinet and chief of staff to the Ministry of Defence, headed by Prime Minister Winston Churchill. Knighted in 1940 and promoted full general in 1944, he accompanied Winston Churchill to all major war conferences of Allied leaders. He retired from the army in 1946 and received a barony for his wartime services in 1947. In 1951, Lord Ismay was appointed secretary for Commonwealth relations in Churchill's cabinet and a year later he became the first secretary general of the North Atlantic Treaty Organization and vice chairman of the North Atlantic Council. He retired from office in 1957.

ISNARD, ês-nâr', Maximin, French political leader: b. Grasse, France, Feb. 16, 1755; d. there, March 12, 1825. A perfumer at Draguignan, he was elected in 1791 to the Legislative Assembly, where he joined the ranks of the Girondists, the moderate republican party. Re-elected to the National Convention in 1792, he voted for the execution of Louis XVI in January 1793 and served on the Committee of General Defense until its dissolution in April. Opposing the demands of the more radical Jacobins, he was finally ordered arrested in October, but was able to hide with friends until the Reign of Terror ended in July 1794, after which he was recalled to the National Convention. He served (1795-1797) on the Council of Five Hundred, one of the legislative bodies under the Directory, and later supported Napoleon I and Louis XVIII, escaping the prosecution of Convention regicides in 1816.

ISOBAR, i'sô-bâr, in chemistry, a term applied to atoms having the same mass but different atomic numbers. The term was unknown in chemistry until the discovery of isotopes (q.v.), since each element was thought to be made up of atoms of the same mass. The simplest example of isobars is that of an isotope of helium and one of hydrogen. Helium with two protons and one neutron in the nucleus is He³, while the isotope of hydrogen which has one proton and two neutrons in its nucleus is tritium, H³. A special case is

that of "isobaric isotopes," in which a single element may exist in two forms with the same atomic weight and the same atomic number. One form loses gamma rays only to produce the second, which in turn disintegrates to produce another element in the usual radioactive fashion. The two have different half lives.

W. T. READ.

ISOBAR, in meteorology, a line on a weather map passing through points of equal barometric pressure, after reduction thereof to sea level or some other constant-altitude equivalent. Isobars are averaged curves, usually drawn on surface or upper-air charts for each 3 or 5 millibars of atmospheric pressure difference. See also METEOROLOGY.

ISOCLINES. See FOLDS.

ISOCLINIC LINES, i-sô-klin'ik, on geomagnetic charts, lines passing through all points on the earth's surface at which the inclination or dip of a magnetic dipping needle (q.v.) is the same. See also TERRESTRIAL MAGNETISM.

ISOCRATES, i-sôk'ra-têz, Athenian orator and rhetorician: b. Athens, Greece, 436 B.C.; d. there, 338 B.C. His inclusion in the ancient canon of the so-called Ten Attic Orators was not on account of his publicly pronounced orations, for his weak voice and natural nervousness hindered him from speaking often in public; but his speeches, composed for others to deliver, were considered the most artistic specimens of Attic Greek. His extant addresses avoid hiatus, crasis (vowel contractions), and dissonance, and are distinguished for their purity of diction, harmonious rhythm, elaborate periods, and symmetrical structure.

Beyond his mastery of the rhetorician's craft, Isocrates' claim to fame rests on two other foundations: his pedagogy and his patriotism. In his school of oratory (c. 392-c. 350 B.C.) at Athens, he trained almost all the noted Greek orators, politicians, philosophers, and historians of the 4th century B.C. These pupils—each in his own way—developed the principles taught by Isocrates and through these precepts profoundly influenced Greek (and, afterward, Latin) prose. Three centuries later, Marcus Tullius Cicero, Rome's greatest orator, characterized the school as "the laboratory of eloquence"—perhaps the best tribute ever paid to Isocrates' instruction.

In politics Isocrates looked beyond the independent, provincial Greek city-state to a Hellenism with a worldwide mission. He espoused the establishment of peace and unity among the warring city-states and advocated the adoption of a common cause which would weld the Greeks into a nation. This plan inspired Philip II, king of Macedon (r. 359-336 B.C.), to unite the Greek city-states into a Panhellenic union to conquer the East. Philip's death did not delay his program, which was completed by his son Alexander III the Great (r. 336-323 B.C.). His successors, Seleucids in Asia and Ptolemies in Africa (Egypt), continued for three centuries the Hellenization of those areas with such success that Greek culture persisted in the East, even after the Roman conquest, until it gradually was submerged by the rising tide of Islam, which began to beat upon it in the 7th century.

Of the 60 orations attributed to Isocrates in

antiquity, only 28 were accepted as authentic; 21 survive together with 9 letters, mostly addressed to kings. His speeches fall into the following categories: (1) educational—two discourses criticizing other disciplines and commending his own method; (2) forensic—six speeches for clients in private lawsuits; (3) hortatory—three orations on morals; (4) epideictic—three encomiums, of which the one on Evagoras, king of Salamis in Cyprus (r. 411-374 B.C.), is the earliest Greek biography extant; and (5) political—six addresses on government and policies (mainly Athenian), of which the *Panegyricus*, the *Areopagiticus*, and the *Panathenaicus* are the most celebrated. Besides these orations and letters we have 26 titles and 41 fragments of other orations and 6 short quotations from a lost treatise on the art of rhetoric.

The best Greek edition with English translation is by George Norlin and Larue van Hook, *Isocrates* (3 vols., 1928-45).

ISODYNAMIC LINES, i-sô-dî-nâm'ik, on geomagnetic charts, lines passing through all points possessing equal values of horizontal intensity in the earth's magnetic field. See also TERRESTRIAL MAGNETISM.

In climatology, isodynamic lines on a climatic chart of a region are lines which pass through places having equal average surface wind velocities.

ISOGLOSS, i'sô-glôss, in linguistics, a plotted line on a map marking the limits within which certain languages, dialects, or types of pronunciation are used. Refinements of the isogloss are the *isolex*, to mark areas where identical words are used; *isophone*, marking areas of identical pronunciation; *isotax*, for areas with identical syntactical features; and *isoseme*, indicating areas of identical meaning.

ISOGONIC LINES, i-sô-gôn'ik, on a geomagnetic chart, lines passing through all points having equal magnetic declination (or variation); that is, all points where a magnetic compass needle has the same angular departure from a true north-south plane. Magnetic declination is caused by the fact that the earth's north and south magnetic poles do not coincide with the geographic poles, but lie equatorward of these true poles in both cases. The curved line passing through all points of zero magnetic declination (that is, where the direction of the geographic poles coincides exactly with that of the magnetic poles) is termed the *agonic line*. Two sections of this line exist, in the Western and Eastern hemispheres respectively. At any point east of the American agonic line, between it and the looping Eurasiatic-Australian section, a compass points west of the geographic pole in either northern or southern latitudes; westward from the American agonic line in both latitudes, as well as north of the central Asiatic loop, a compass points east of the geographic pole. Magnetic declinations increase up to a maximum of 180°, east or west, as indicated by the isogonic lines. See also COMPASS, MAGNETIC; TERRESTRIAL MAGNETISM.

ISOLATING LANGUAGES. See GRAMMAR; LANGUAGES OF THE WORLD—*Methods of Classification*.

ISOLATING MECHANISMS, ī-sō-lāt-īng mēk'ā-nīz'ms, in biology, barriers which prevent or curtail the exchange of genes between populations of sexually reproducing organisms. Such isolating mechanisms may be spatial, as when the populations inhabit separate geographical territories; or they may stem from genetically determined properties of the populations which result in a failure of interbreeding even among populations coexisting in the same territory. A primary distinction can thus be drawn between geographical isolating mechanisms and reproductive isolating mechanisms. The former are characteristically present between races of one species; the latter are developed between species. Reproductive isolating mechanisms can be further subdivided into external and internal barriers, depending on whether the gene exchange is blocked before or after cross-fertilization between individuals of the different populations. Examples of external reproductive isolation are the adaptations of different populations to different ecological niches, the occurrence of the mating or flowering periods at different seasons, and specific courtship patterns which stimulate sexually only individuals of the same species. Failure of the sperm or pollen to function in the sexual ducts of another species, inviability of hybrids, and hybrid sterility exemplify the class of internal reproductive isolating mechanisms. See also EVOLUTION.

VERNE GRANT.

ISOLATION, in biology. See ISOLATING MECHANISMS.

ISOLATION, ī-sō-lā'shūn, in physics and chemistry, the separation of one object, material, or substance from its surroundings, for purposes of examination, identification, or use. The first method of isolation which naturally comes to mind involves the difference in density between two or more materials. In metallurgy, for example, a dense material like native gold can be isolated in water by grinding ore or taking already finely divided sand or silt from stream beds and agitating the mixture so that the gold settles to the bottom, while the lighter material floats away. On the other hand, gold may be dissolved in cyanide solutions or in metallic mercury, with which it forms an amalgam. In the course of a large-scale cyaniding operation, it is necessary to get rid of two materials—a coarse grit and a fine slime—before the gold can be isolated from solution. In a piece of chemical engineering equipment known as a classifier, the two are agitated by rakes, which move the solid up an inclined plane in partial suspension in the solution. The “fines” float away in one direction, to be separated subsequently from the liquid by settling, while the grit is raked over the upper edge of the sloping floor of the classifier.

Rare-earth elements are isolated as soluble compounds by virtue of the difference between the rates of adsorption in a column of an inert material. Electrical charges imposed on small particles bring about isolation of dusts and mists from gases as they pass through a corona discharge; the solids and liquids go to a discharge electrode, leaving a harmless gas to escape into the air.

All qualitative and quantitative analysis, and all organic preparations, to say nothing of most chemical engineering processes, depend on the phenomena of isolation, in which one substance is dissolved, or converted to another derivative which it insoluble. To determine the chloride-ion content of a solution, insoluble silver chloride is isolated, dried, and weighed. Magnesium, present in very low concentration in sea water, is converted by lime to insoluble magnesium hydroxide, which is isolated by filtration for subsequent conversion to the chloride, and thence to the metal.

W. T. READ,
Chemical Consultant.

ISOLATIONISM, ī-sō-lā'shūn-īz'm, in diplomacy, a policy of maintaining a nation's rights and interests without alliances. When a nation's geopolitical position is such that it can do so, it is in a fortunate situation, because alliances always involve one in the diplomatic liabilities of one's allies and have to be paid for with diplomatic equivalents. Japan, before its pact with Great Britain in 1902, lived without allies for a thousand years, during the last half century of which it grew to world power. Great Britain lived from 1822 to 1902 in “splendid isolation” with only *ad hoc* (temporary) allies, except for a dormant traditional alliance with Portugal. The United States dwelt successfully in diplomatic isolation from 1800 to 1917—if not, indeed, to 1941. Its experience is an example of some of the national isolationist trends of the 19th century.

American Isolationism: 1776-1900.—Up to the time of the American Revolution the English colonists in North America, remote though they were from England, had no concept of isolation. They regarded involvement in Great Britain's wars with European states and colonies as an inevitable dispensation of fate, never to be questioned. It took a liberal English isolationist and recent immigrant to the colonies to awaken them to the idea that one of the advantages of independence was separation from Britain's wars and quarrels with other peoples. “Any submission to or dependence upon Great Britain,” Tom Paine reminded his American readers in *Common Sense* (1776), “tends directly to involve this country in European wars and quarrels and sets us at variance with nations who would otherwise seek our friendship and against whom we have neither anger nor complaint.”

American diplomacy at the outset of the Revolution was so set against alliances that the Continental Congress resisted any commitment to France binding the two nations not to make a separate peace. Nevertheless, the need for military assistance overcame the revulsion to an alliance, without which the War of Independence would not have succeeded. The Franco-American alliance of 1778 entangled the United States in France's commitments with other allies (notably Spain, Convention of Aranjuez, 1779) during both the peace negotiations of 1782 and the wars of the French Revolution, and this experience disillusioned American statesmen after independence had been achieved.

President George Washington in his classic *Farewell Address* (1796), drafted by Alexander Hamilton, counseled his fellow countrymen to steer clear of foreign entanglements: “The great rule of conduct for us, in regard to foreign nations, is in extending our commercial relations, to have with them as little *political* connection as

possible. . . . Europe has a set of primary interests, which to us have none, or a very remote relation. Hence she must be engaged in frequent controversies the causes of which are essentially foreign to our concerns. Hence, therefore, it must be unwise in us to implicate ourselves, by artificial ties, in the *ordinary* vicissitudes of her politics, or the *ordinary* combinations and collisions of her friendships or enmities." President Thomas Jefferson echoed this advice in his inaugural address of 1801: ". . . peace, commerce, and honest friendship with all nations, entangling alliances with none." President James Monroe re-echoed the policy of Washington and Jefferson in his famous message to Congress of Dec. 2, 1823, known since 1852 as the Monroe Doctrine. Recalling the two separate spheres of polity laid down for the New World and the Old World, he declared: "In the wars of the European powers, in matters relating to themselves, we have never taken part, nor does it comport with our policy, so to do. *It is only when our rights are invaded, or seriously menaced* that we resent injuries, or make preparations for our defense"

The United States had considered its neutral rights invaded by France in 1796–1798 and had prepared for defense to the extent of a quasi war with that former ally; but it is noteworthy that in that emergency both Congress and President John Adams rejected any idea of an alliance with France's enemy Great Britain. In the years 1806–1812 the United States had considered its sovereign rights invaded by British maritime measures and the practice of impressing seamen, and had gone to war finally in the hope of conquering Canada, and also Florida which belonged to Britain's ally Spain. But the student of diplomatic isolation must note that President James Madison's government rejected any idea of an alliance with Britain's deadly enemy France under Emperor Napoleon I.

The isolationist foreign policy of the United States was remarkably successful throughout the 19th century and well into the 20th. Its success can be explained by the following geopolitical circumstances and factors: (1) the country occupied a detached and distant position; (2) Europe's distresses were America's advantage, leaving the Continental powers little energy for adventures in North America; and (3) Canada was in effect a hostage for good relations with Great Britain, the only power that was in a position to make war on the United States. Isolation was successful, in short, because of the foolproof geopolitical situation of the United States. That it was foolproof is attested by the fact that it was able to indulge in a great civil war without any permanent harm to its foreign policy.

Changes Since 1900.—This happy condition changed at the beginning of the 20th century with the rise of Germany and Japan as world powers on the opposite side of each ocean, each with a first-class army, each building a first-class navy, and neither with a hostage like Canada for good conduct toward the United States. On the contrary, the United States had given a hostage to Japan by the acquisition of the Philippine Islands (1898).

Americans were slow to realize the implications of this new world picture of power and politics. Isolation persisted as a policy until Germany finally challenged President Woodrow Wilson's defense of neutral rights by proclaiming unrestricted submarine warfare on Jan. 31,

1917. Isolation broke down during the joint war effort of 1917–1918, but even then the United States made no alliances with Germany's enemies; President Wilson insisted that the partners of the United States in the war were associates, not allies. After the war, when American rights and interests seemed no longer menaced, the nation reverted to complete diplomatic isolation by rejecting the Treaty of Versailles and the Covenant of the League of Nations and repudiating, in the neutrality legislation of 1935–1937, Wilson's whole system of diplomacy.

Only when American rights and interests were menaced by the conquests of dictators Adolf Hitler and Benito Mussolini and their Tripartite Alliance of 1940 (with Japan), the United States again prepared for defense and deserted the outworn tradition of isolation. The changing geopolitical situation made it no longer safe to live without allies; in the face of the postwar menace of the Soviet Union and its Eurasian allies, it became even more dangerous.

"We have pinned our hopes to the banner of the United Nations," President Harry S. Truman declared to Congress on Jan. 14, 1946, after the defeat of Germany and Japan. From 1947 to 1955 a spectacular revolution in American foreign policy, backed by bipartisan domestic political support, resulted in defensive regional alliances with 44 sovereign nations, within the purview of Article 51 of the United Nations Charter. In the atomic age, isolation has become a thing of the past.

As to cultural isolationism, there has never been much in the history of the United States. No people has been more influenced by foreign cultures than the people of the United States, and in recent years no people has had greater influence on other peoples and nations. Contemporary examples of cultural isolation are found, however, in the Communist regimes of Russia, China, and their satellites, which mold their cultures and even their science to their own political concepts, insulated from outside cultures by the Iron Curtain and Bamboo Curtain.

ISOMERISM, i-sōm'ēr-iz'm, a term used in chemistry to describe the phenomenon in which two or more compounds have the same elements, the same percentage of each element, and the same

molecular weights, but show differences in either physical properties, chemical properties, or both. Such compounds, called isomers, possess identical molecular formulas but have different structural formulas; that is, the atoms are arranged or united in different ways in the molecules constituting each isomer. The phenomenon is of frequent occurrence, and isomeric compounds are known in both organic and inorganic chemical fields. There are two main types of isomerism exhibited by organic compounds: simple structural isomerism and stereoisomerism.

Simple Structural Isomerism.—Under this heading are four kinds of compounds.

Carbon-skeleton isomers differ primarily in the arrangement of the carbon atoms. For example, there are two butanes with the molecular formula C_4H_{10} whose structural formulas are:

n-butane

isobutane.

There are 3 isomeric pentanes with the molecular formula C_5H_{12} ; 5 isomeric hexanes (C_6H_{14}); 9 isomeric heptanes (C_7H_{16}); 18 isomeric octanes (C_8H_{18}); and 35 isomers of C_9H_{20} . Most of these are known. As the number of atoms in the molecule increases, the number of isomers increases. Mathematical calculations indicate there should be 366,319 isomers of $C_{20}H_{42}$ and 6.25×10^{19} isomers of $C_{40}H_{82}$. Only a few of these are known.

Position isomers are compounds with the same carbon skeleton, but the substituent atoms or groups occupy different positions. Some examples are:

1-chloropropane

2-chloropropane

o-aminobenzoic acid

m-aminobenzoic acid

p-aminobenzoic acid

Functional group isomers consist of compounds with the same molecular formula but different functional groups; that is, they belong to different homologous series. For example, ethanol (CH_3CH_2OH) is isomeric with methyl ether (CH_3OCH_3); both have the molecular formula C_2H_6O .

Tautomers are also functional group isomers, but these are in dynamic equilibrium with each other. For example, ethyl acetoacetate ($C_6H_{10}O_3$) exists as an equilibrium mixture of

These tautomeric isomers have been separated.

Combinations of the above are also known. For example, two of the many isomers of C_4H_7ClO are:

4-chloro-2-butanone

2-chloro-2-methylpropanal.

These differ in the carbon skeleton, functional groups, and position of attachment of the halogen.

Stereoisomerism.—Isomeric compounds are known which have the same carbon skeleton and the same functional groups attached in the same positions but which show experimental differences in certain physical and/or chemical properties. To explain this phenomenon, it is necessary to postulate differences in the three-dimensional space arrangements of the atoms or groups within the molecules. Two main types of stereoisomers are known: geometric isomers and optical isomers.

Geometric isomers owe their existence to the fact that atoms or groups occupy fixed positions in space when attached to two doubly bound atoms or to certain cyclic structures. For example, 2-butene (C_4H_8) exists in two geometric isomeric forms:

cis-2-butene

trans-2-butene.

The presence of the double bond fixes the positions of the methyl radicals and hydrogen atoms and prevents rotation or exchange of groups. The first structure has the two hydrogen atoms on the same side of the double bond; hence the prefix *cis*-. In the second formula the hydrogen atoms are across from each other; hence the prefix *trans*-. The doubly bonded atoms can involve elements other than carbon. For example:

anti-azo *syn*-azo.

Cyclic structures also constitute a fixed spatial reference system so that geometric isomers can arise, as in the following:

a *cis*-dibasic acid

a *trans*-dibasic acid.

Other molecular structures are known which orient attached groups in definite spatial positions which give rise to geometric isomers.

Optical isomers are of two types, enantiomorphous isomers and diastereomers. The first type, enantiomorphous, is characterized by a molecular structure such that it possesses a nonsuperposable mirror image. Such molecules may contain an asymmetric carbon atom; that is, a carbon

atom linked to four different radicals (Joseph LeBel, Jacobus van't Hoff, 1874). To express the three dimensional arrangements possible it is necessary to use space models or projections of these. As an example of enantiomorphs, the optical isomers of 2-butanol ($\text{CH}_3\text{CHOHC}_2\text{H}_5$) may be illustrated, using the van't Hoff concept of a tetrahedral carbon atom.

Inspection of the models (A) and (B) shows that they are mirror images of each other but are not identical because the figures are not superposable (that is, not congruent). Such isomers resemble each other very closely and can be distinguished from each other only by their influence on plane-polarized light using an instrument called a polarimeter. One isomer, marked (+), rotates the plane of vibration of polarized light in a clockwise direction and is denoted as dextrorotatory; the mirror image, (-), rotates the plane counterclockwise and is called levorotatory. When careful measurements are made using the same length of tube containing the liquids (or solutions of the same concentration) at the same wavelength of light and same temperature, it is found that the degrees of rotation are equal in magnitude but opposite in direction. It is from this physical property (optical effects) that the isomers are called optical isomers. The central asymmetric atom need not be carbon; it can also be nitrogen, silicon, arsenic, or any other element whose valences are tetrahedrally directed.

Diastereoisomers (or diastereomers) are optical isomers but not enantiomorphs. For example, ordinary corn sugar, glucose ($\text{C}_6\text{H}_{12}\text{O}_6$) exists in two diastereomeric forms:

The two forms differ only in the configuration about the carbon atom marked with the asterisk; the α -form has an optical rotation of $+112^\circ$ whereas the β -form rotates polarized light $+18.7^\circ$. The structures are not mirror images. These diastereomers in the sugar series are also called anomers.

An asymmetric atom is not essential for the existence of optical isomers; any three-dimensional structure with proper substituents which possesses a nonsuperposable mirror image can

exhibit optical isomerism. Optically active isomers (+) and (-) have been obtained from allenes:

They have also been obtained from other three-dimensional compounds such as substituted phenanthrenes, tri-*o*-thymotide, arylolefins, polynuclear aromatic hydrocarbons, ansa compounds, and hexasubstituted cyclohexanes (inositols, benzene hexachloride).

Inorganic compounds also exhibit the phenomenon of isomerism, most of the examples being in the field of coordination compounds. An example of structural isomerism is shown by the two coordination compounds of cobalt:

In compound (I) the bromine is in the cation and the sulphate group is the anion; whereas in structure (II), the bromine is the anion and the sulphate group is in the cationic complex.

Coordination compounds of cobalt, in which six groups are attached to the central cobalt atom by bonds which are directed to the apexes of an octahedron, can also exist in geometric isomers. For example:

Elements with a planar distribution of valences also exist as geometric isomers. For example, cis- and trans-isomers of nickel bis-benzylmethylglyoxime, of the palladous complex with glycine, and the platinum complexes with pyridine and dialkyl sulphides are known.

Many examples of optical isomers of complex compounds of Co, Al, As, Ir, Rh, Cr, Fe, Pt, and Zn are known. These are also octahedral coordina-

tion complexes in which the central metal is attached to six groups. When these are properly chosen, structures possessing nonsuperposable mirror images result, and optical isomers become possible. One example may illustrate the three-dimensional structure for dextro- and levo-isomers of this type.

Modern usage excludes the phenomena of polymerism and polymorphism as subdivisions of isomerism. Polymers constitute a class of high molecular weight substances characterized by the presence of structural repeating units; they do not fall under the definition of isomers. Polymorphism is related to the crystalline state.

All these types of isomers are composed of ordinary elements with ordinary isotopic composition, as the materials available from plants, animals, and their remains (coal, petroleum). Isotopic compounds such as CH_4 and CD_4 are not isomers; their percentage composition and molecular weights are different. Likewise, $\text{CH}_3\text{O}^{16}\text{H}$ and $\text{CH}_3\text{O}^{18}\text{H}$; C^{12}O_2 and C^{14}O_2 ; and N^{14}H_3 and N^{15}H_3 are classed as different compounds and not as isomers. The presence of an isotopic form of an element can give rise to isomers in certain structures. For example, optical isomers of $\text{C}_6\text{H}_5\text{CHDCH}_3$ are known because of the asymmetric carbon atom (*) which gives rise to nonsuperposable mirror image structures.

Likewise, cis- and trans-isomers may exist in isotopically substituted olefins such as:

ISOMORPHISM, i-sô-môr'fiz'm, signifying a similarity in form between things, a term used in (1) crystallography, mineralogy, and chemistry; (2) biology; (3) mathematics.

In crystallography, mineralogy, and chemistry, isomorphism means a similarity of crystalline form between substances of analogous chemical constitution. The word was introduced by Eilhardt Mitscherlich in 1819, but the phenomenon had been discovered in 1812 by William Hyde Wollaston, who observed that crystals of the carbonates of barium, strontium, and lead, for instance, are very similar in shape, and that the interfacial angles are very similar though not identical. We now know, as a result of X-ray diffraction studies, that this similarity of crystal shape arises from a very close similarity in the arrangement of the atoms.

The recognition of the phenomenon of isomorphism was of great importance in the development of chemistry in the 19th century. In a pair of isomorphous crystals it was assumed that the atoms were present in the same relative numbers, so that if the valences of the atoms in one crystal were known, those in the other could be inferred. In this way the isomorphism of sodium sulphate and sodium selenate led to the correct valence and thence to the correct atomic weight for selenium, and the isomorphism of the minerals vanadinite and apatite led to the classification of vanadium with phosphorus in group 5 of the periodic table.

Crystals of substances of analogous chemical constitution are not necessarily isomorphous: crystals of MgCO_3 , ZnCO_3 , FeCO_3 , and MnCO_3 for instance, though they form an isomorphous group (of rhombohedral symmetry) among themselves, are quite different from those of BaCO_3 , SrCO_3 , and PbCO_3 , which have orthorhombic symmetry. The difference of crystal structure arises from a difference in the sizes of the metal ions in relation to the carbonate ion: small metal ions pack with carbonate ions to give a rhombohedral arrangement, while larger metal ions give a quite different orthorhombic arrangement. The calcium ion is of intermediate size, as a result of which CaCO_3 can assume either of these structures; this is an example of isodimorphism.

Some substances which form isomorphous crystals can also crystallize together as "mixed crystals" containing both substances; in simple ionic crystals this occurs only if the corresponding ions have the same valence and do not differ in radius by more than about 15 per cent. Thus K_2SO_4 and Rb_2SO_4 form mixed crystals, since the monovalent metal ions are closely similar in size; but NaNO_3 and rhombohedral CaCO_3 (a closely isomorphous pair) do not form mixed crystals, because the ions are monovalent in NaNO_3 but divalent in CaCO_3 . The classification of minerals largely depends on isomorphous relations and the formation of mixed crystals; in certain complex minerals, especially silicates, the limitations of valence, ionic size, and relative numbers of the different atoms are less stringent, and there is, for instance, a complete range of mixed crystals of the triclinic feldspars albite $\text{NaAlSi}_3\text{O}_8$ and anorthite $\text{CaAl}_2\text{Si}_2\text{O}_8$.

Isomorphism is of great importance in the determination of the atomic positions in complex crystals by X-ray diffraction methods. A powerful direct method is based on a comparison of the diffraction patterns of a pair of isomorphous crystals containing ions of very different diffracting power; such a comparison leads to a

knowledge of the phases of the diffracted waves and thence to the calculation of a detailed image of the structure. The method was first used for the alums and for phthalocyanine and its derivatives. See also CHEMICAL CRYSTALLOGRAPHY.

In biology, isomorphism is a similarity of form between organisms of different ancestry, resulting from convergence due to similarity in habits or environment.

In mathematics, isomorphism is similarity of form and of operations between different groups. See also EQUATION—2. *Galois Theory of Equations* (Isomorphic Fields); GROUPS, THEORY OF—*Isomorphisms*.

ISONZO RIVER, ê-zôn'tsô or **SOCA RIVER**, sô'châ (ancient SONTIUS), a river in northwest Yugoslavia and northeast Italy, 84 miles long, rising in the Julian Alps in Slovenia and flowing generally southward past Kobarid (Ital., Caporetto) and Tolmin in Yugoslavia, and Gorizia in Italy, to the Gulf of Trieste in the Adriatic Sea, 12 miles northwest of Trieste. In World War I the Isonzo Valley was the scene of many battles between the Italians, whose territory it then was, and the Austrians and Germans. After World War II, at the Conference of Paris in 1946, most of the Isonzo Valley (above Gorizia) was given to Yugoslavia, where the river is known as the Soča.

See also WORLD WAR I—9. *Italian Front* (First Four Battles of the Isonzo) and (Fifth Battle of the Isonzo).

ISOPODA, i-sôp'ô-dâ, an order of Crustacea under the subclass Malacostraca. The body is dorsoventrally flattened. A head with eyes and antennae and mouth parts underneath is followed by seven free thoracic segments, all or some of which bear a pair of walking legs; after this comes an abdomen of six segments, often indistinct through fusion, bearing flattened leaflike respiratory and swimming appendages. These animals are generally small, the size of insects, but a deep-sea form reaches a foot in length. The group varies greatly in form and mode of life, having marine, fresh-water, terrestrial, and parasitic members. The majority are marine and are common along shores, hiding under objects or living among seaweeds. One marine isopod, *Limnoria*, known as the gribble, is, despite its minute size, very destructive to piling by burrowing into the wood. Parasitic forms include the scarcely altered Cymothoidae, infesting fishes and whales, and the much altered Cryptoniscidae and Bopyridae, parasites of other crustaceans. The terrestrial isopods are the familiar sow bugs or pill bugs, flattened gray creatures found under flowerpots, boards, fallen logs, and the like, some of which roll themselves up like an armadillo on disturbance. The similar fresh-water isopods are common in ponds and streams. Isopods in general are scavengers, feeding on corpses and decaying matter. They breed only by the sexual method; the sexes are separate and distinguished by differences in the form of some of the appendages.

The eggs are brooded in a brood chamber, formed by basal expansions of some of the thoracic legs, and hatch as young isopods.

Consult Richardson, Harriet, *A Monograph on the Isopods of North America*, United States National Museum, Bulletin No. 54 (Washington 1905); Van Name, Willard Gibbs, *The American Land and Fresh-Water Isopod Crustacea*, The American Museum of Natural History, Bulletin No. 71 (New York 1936).

LIBBIE H. HYMAN,
The American Museum of Natural History.

ISOSTASY, i-sôs'tâ-sî, in geology and geodesy, the tendency of adjacent portions of the earth's crust to seek an equilibrium state of balance by adjusting their varying weights of rock material against the downward force of gravity. Although several hypotheses concerning the nature of this dynamic action were earlier proposed, the term "isostasy" was first used by an American geologist, Clarence E. Dutton, in 1889.

The principle of isostasy is somewhat analogous to that of a balance scale. As the pan of one side is overloaded, it sinks under the action of gravity. In compensation, the opposite pan rises until its load is so adjusted that a state of equilibrium is reached, after which no further vertical displacement takes place. The theory of isostasy similarly assumes the disposition of certain naturally occurring excesses and deficiencies of density in the earth's outer rock mantle to make such a balanced condition possible.

Early surveys by Pierre Bouguer (1698-1758) in the Andes of Peru and by the English mathematician Joseph H. Pratt (1811-1871) in the Himalaya Mountains of India revealed that the attraction of these great masses for a pendulum was considerably less than it should have been according to the theory of gravitation. From this fact it was later deduced that a condition of isostatic compensation must prevail in the earth's crust, in which a rock material of lesser density lies beneath upthrust surface features and a material of greater density exists beneath land depressions and oceanic basins.

According to the "roots of the mountains" theory proposed by Sir George Biddell Airy in 1855, the continental crust of the earth consists chiefly of rock material rich in silica and alumina (termed, from the first two letters of each word, the *sial*), which because of its lesser density "floats" on a heavier layer of magmatic material rich in silica and magnesium (termed the *sima*) which also predominates beneath ocean basins. The first of these two layers is principally granitic in composition; the second is primarily basaltic. (See BASALT; GRANITE.) The principle by which isostatic balance is achieved by this sialic layer through varying degrees of downward penetration into the sima is shown in Fig. 1.

Fig. 1. Airy theory of isostasy.

A second theory of isostasy proposed by Pratt in 1856 assumes that the density of land masses of differing heights is compensated at a uniform depth by underlying land blocks having various densities and volumes, as depicted in idealized form in Fig. 2.

Fig. 2. Pratt theory of isostasy.

Modern studies of isostasy are carried out by the Isostatic Institute of the International Association of Geodesy in Helsinki, Finland. New data were also found by seismic and gravimetric studies in the International Geophysical Year (q.v.). See also EARTH, THE—*Earth's Constitution*.

ISOTOPES, ī'sō-tōps, in chemistry and physics, atoms of the same chemical element having the same atomic number but different radioactive properties and atomic weights. For many years it was believed that all atoms of a particular element were identical in size and atomic weight. Early in the present century, however, the existence was established of several groups of radioactive elements having different radioactive properties and atomic weights, but identical chemical behavior. This led Frederick Soddy to describe these elements as isotopes (from Gr. *isos*, equal, + *topos*, place), since the elements within each group occupied the same place in Dmitri Ivanovich Mendeleyev's periodic table (see PERIODIC LAW). The existence of stable isotopes was suggested by the work of Joseph John Thomson on positive rays from the gas neon (1913), and the subsequent development of the mass spectrograph by Francis William Aston in 1919 quickly led to confirmation that most chemical elements consist of mixtures of a few isotopes, the atomic weight of the element being the mean weight of the atoms of that element.

Modern physical theory suggests that the atom consists of a dense nucleus surrounded by a cloud of electrons describing orbits around the nucleus. The nucleus is an assembly of neutrons and protons, both called nucleons, which are particles of nearly equal weight. The neutron, as the name suggests, is a neutrally charged form; the proton carries a unit positive electrical charge. The electrons are light particles weighing little more than $\frac{1}{2000}$ part of the weight of a proton (nucleon), and carrying a unit negative charge. The number of orbital electrons equals the number of protons in the nucleus so that the atom as a whole is electrically neutral. The number of protons determines the nuclear charge as well as the number of orbital electrons, and therefore the

chemical behavior of the atom; the number of neutrons determines the isotopic weight. Thus the isotopes of an element consist of atoms having within their nuclei the same number of protons but different numbers of neutrons. An isotope is normally specified by the chemical symbol which determines the nuclear charge, together with a superscript which specifies the mass number or the total number of nucleons in the nucleus. For example, Mg^{24} specifies the isotope of magnesium (charge 12 units) which has 24 nucleons, that is, 12 protons and 12 neutrons. The symbol is sometimes written as $^{24}_{12}\text{Mg}$. As an example of the physical differences between chemically identical isotopes, the lighter uranium isotope U^{235} , when extracted by a mass spectrograph or other means from relatively harmless natural uranium, becomes one of the materials from which an atomic bomb may be constructed. This is because it is able to undergo a fast fission chain reaction.

In addition to the stable and radioactive isotopes occurring in nature, many more radioactive isotopes can be produced artificially. In 1934, Irène Curie and her husband Frédéric Joliot-Curie produced artificially a radioactive isotope of phosphorus (P^{30}) by bombarding aluminum with alpha particles (helium nuclei consisting of two protons and two neutrons). Thereafter many more artificial radioactive isotopes were discovered. Enrico Fermi showed that slow neutrons are particularly effective as bombarding particles in this connection, since they are uncharged and easily enter a nucleus and become part of it, producing a different isotope. Vast quantities of radioactive isotopes are now produced by this method in nuclear reactors or piles. Many of these, now available at reasonable cost, are used in industry as well as in science and medicine.

One of the first uses of radioactive isotopes was as tracers; natural radioactive isotopes were used in this way by Georg von Hevesy and Friedrich Adolf Paneth in 1913. The radioactive tracer atoms are, so to speak, labeled by the radiations which they emit. They can move about in chemical and biological processes just as the other nonradioactive atoms of the same element. The position of the labeled atoms can, however, be determined with great sensitivity at some later time by the detection of the radiations emitted, and so can demonstrate the movement or exchange of atoms in the process being studied. As an illustration, radioactive phosphorus (P^{32}) has been used by surgeons to determine the position of brain tumors. The tumor tissue selectively absorbs phosphorus from the blood stream, so that if a little radioactive phosphorus is introduced it tends to migrate to the tumor and to betray its presence by its radioactivity. Radioactive tracers have also been used for studying wear in engine cylinders, the migration of insects, and many other interesting problems.

Radioactive sources of very high intensity can be produced artificially in a reactor. Radioactive cobalt (Co^{60}) has now largely supplanted radium and other natural radioactive elements in radiotherapy because, in addition to emitting radiations of a suitable nature for this work, it can be produced in a convenient mechanical form and is comparatively cheap. Similar strong sources of radiation are finding uses in radiography, in sterilization of foodstuffs, in reducing static electricity in industrial processes, and in many other fields.

ISRAEL, a republic of southwestern Asia, proclaimed on May 14, 1948, upon the termination of the British mandate over Palestine. It is bounded on the north by Lebanon, on the east by Syria and Jordan, on the southwest by the United Arab Republic, and on the west by the Gaza Strip and the Mediterranean Sea. The total area is 7,993 square miles, or about three fourths that of the former mandate. As of Jan. 31, 1963, the population was estimated at 2,338,000. The capital is Jerusalem,¹ with a population of 167,435 at the 1961 census. Other large cities, with their 1961 populations, are Tel Aviv-Jaffa (386,070), Haifa (183,031), and Ramat Gan (90,841). The national flag contains the six-pointed star of David set between two horizontal blue stripes on a white field. The national anthem is *Hatikvah*, with words by Naphtali Herz Imber.

The land, people, economy, culture, and history of Israel are discussed under the following headings:

- | | |
|-------------------------------|--------------------------------|
| 1. The Land and Its Resources | 4. Education and Cultural Life |
| 2. The People | 5. Government |
| 3. Economic Activities | 6. History |
| | 7. Bibliography |

1. THE LAND AND ITS RESOURCES

In shape, Israel is an irregular, narrow strip

¹On Dec. 9, 1949, the United Nations General Assembly declared Jerusalem to be an international area under the UN Trusteeship Council. Both Israel and the Hashemite Kingdom of Jordan (formerly Transjordan) rejected the United Nations resolution, and Jerusalem remained divided between the Israeli-held New City and the Old City, held by Jordan.

approximately 265 miles long, extending from the Galilean hills in the north to the port of Elath (Eilat) in the extreme southeast. The highest altitude is at Mount Jarmaq (Meirun, Meron), a 3,963-foot peak in upper Galilee; the lowest is along the shores of the Dead Sea (1,292 feet below sea level), the lowest point on the world's surface. Israel's coastline on the Mediterranean Sea extends for 117 miles; on the Dead Sea, for 35 miles; and on the Red Sea, for 6 miles.

National emblem

Mountain and plain, lake and seacoast, field and desert vary Israel's landscape. Newly productive soil adjoins barren stretches, sharpening the contrasts produced by the rapid reclamation of wasteland. From the coastal plain—warm and moist in summer, mild in winter—the land rises eastward to the Judean heights and then drops markedly to the hot and dry Jordan Valley. In the south lies the Negev (Negeb) Desert, constituting about half the area of the country. Hot and dry in summer, cold and dry in winter, the Negev is Israel's chief frontier area. In the north are the Galilee hills, warm and dry in summer, cold and rainy in winter; and the rich agricultural lands of the Jezreel Valley, reclaimed from malarial swamps.

Israel's chief source of mineral wealth is the Dead Sea, of which 108 square miles lie within its territory. The sea's abundant chemical deposits yield potash, caustic soda, magnesium, and bromine. The country also possesses ingredients for cement and other building materials, ceramic clays and glass sand, mica, barite, feldspar, sulfur, peat, and papyrus. Copper lies in the hills of the southern Negev, and deposits of phosphates, kaolin, and iron ore have been found. Commercial exploitation of petroleum began at Helets (Helez), near Ashkelon, in 1955.

See also DEAD SEA; JORDAN RIVER.

2. THE PEOPLE

Population Trends.—At the proclamation of the state in 1948 the Jewish population approximated 655,000. An unprecedented wave of immigration resulted in a doubling of the population within three years. By the time of the census of May 22, 1961, the population totaled 2,183,332, including 247,134 non-Jews. Hebrew is the official language of the country and also the common language of the majority of the people. The non-Jewish population consists chiefly of Arab Muslims in rural villages in Galilee and elsewhere and of about 27,000 Bedouins.

Despite the establishment of many new rural settlements in the Negev and elsewhere, approximately 33 percent of the population in 1961 lived

in the three major cities of Tel Aviv-Jaffa, Haifa, and Jerusalem; 44 percent, in other towns and townships; and 23 percent, in the countryside. Vital statistics reflect the predominantly urban and Western character of the Israelis, as well as the effectiveness of medical and health facilities. The crude birth rate in 1961 was 25.4; the death rate, 6.0; and the infant mortality rate, 31.4. The average life expectancy at birth for the Jewish population in 1960 was 70.7 years for males and 73.5 for females.

Immigration.—In accordance with its policy to "welcome home every Jew who seeks entry," the new nation accepted 700,000 immigrants in the first four years of its existence. The majority of the Jewish population under the British mandate had come from the Jewish centers of eastern and central Europe during the waves of Zionist settlement between World Wars I and II. In the period 1948-1951 the greatest proportion of immigrants (about 45 percent) also came from eastern Europe, but an increasing number arrived from Asia and northern Africa, where the surge of Arab nationalism threatened many of the ancient Jewish communities. By late 1951 the rate of influx had lessened, and in succeeding years the number of newcomers rose and fell, partly reflecting political conditions in the countries of origin.

The vast and sudden influx in the first few

available. The principal role in the practical work of immigration, absorption, and agricultural settlement has been undertaken by the Jewish Agency, the division of functions between the agency and the government of Israel having been defined in the World Zionist Organization Law of 1952 and a covenant of 1954.

Religion.—The great majority of the inhabitants are of the Jewish faith, but only a relatively small proportion of the population accepts the full orthodox code and ritual. Questions of religious control in education, personal status (chiefly marriage and divorce), observation of kosher food laws and of the Sabbath, and recruitment of women for national defense are often important national issues. The Israeli government, through the Ministry of Religious Affairs, assists and safeguards the Jewish, Muslim, and other religious communities in the conduct of religious affairs and the maintenance of places of worship. Religious officials are paid by the government. Autonomous religious courts of the respective communities have jurisdiction in matters of personal status. The non-Jewish population in 1961 included about 172,000 Muslims (mainly of the Sunnite sect), 52,000 Christians (mainly Greek Catholics and Greek Orthodox), and 24,000 Druzes (Druses). Haifa is the spiritual center of the Baha'i faith. Freedom of worship exists for all groups.

3. ECONOMIC ACTIVITIES

Israel's economy is characterized by an intensive agriculture and by highly specialized light industries. State enterprises, accounting for about 20 percent of all industry, are engaged mainly in the exploitation of natural resources in the Negev. Cooperative and collective organizations are important, particularly in agriculture. Histadrut, the largest labor organization, owns and operates about 15 percent of the nation's industry. As a whole, however, private enterprise is predominant. Dependent on imports for most of its raw materials and many of its foodstuffs and manufactures, the young nation has had to adopt heroic measures to sustain its growing population by developing its internal resources and increasing its output for foreign markets. To encourage private investment, both domestic and foreign, an investment center was established by a law of 1950 (amended in 1955 and 1959), and advantages were offered investors in the form of tax concessions, depreciation allowances, currency transferability, and the right to withdraw profits from the country.

In the first 13 years after the establishment of the state, Israel's population grew by an average of 7 percent annually. The output per worker, however, not only remained undiminished, but rose markedly in this period, reaching an average annual rate of growth of 5 percent in the later years. With foreign aid and investment supplementing domestic capital, the gross national product increased by an average of 10.7 percent annually in the period 1950-1961, one of the highest rates in the world. Despite the almost threefold increase in population from 1948 to 1962, the standard of living rose by more than 50 percent per capita. The austere conditions of the early 1950's were succeeded in the 1960's by a level of living that compared not unfavorably with that of most western European countries.

Industry.—Though lacking the resources for large-scale heavy industry, Israel possesses important assets in its skilled labor force and abundant chemical deposits. The largest industrial

years of the nation's life created a multitude of problems of adjustment and absorption. Among the newcomers were numerous sick and aged persons incapable of self-support. Many immigrants had to acquire new skills and learn a new language. The customs and attitudes of some of the newcomers, particularly those from Africa and Asia, differed considerably from the predominantly European ways of the rest of the population. Within a few years hundreds of thousands of persons had passed through the hastily constructed reception centers and *ma'barot* (transition camps). After 1954 most of the new arrivals went directly to towns or villages, where housing and jobs were

Youths at a school of agriculture for boys and girls at the kibbutz of Ayanot in western Israel near Nes Tsiyona.

Rapho Guillumette

center is located in Tel Aviv and the surrounding area, where textiles and apparel, woodworking and furniture, chemical products, building materials, leather goods, pharmaceuticals, beverages, processed foods, and plastics are produced. Industries in the Haifa region include cement, oil refining, electrical and other machinery, chemicals,

ceramics, glass, tools, and sanitary equipment. Handicrafts and printing are important in the Jerusalem area, while the diamond cutting and polishing industry, a major source of exports, is located in the Natanya (Nathanya, Netanya) district on the coast. Approximately one fourth of the gainfully employed population works in industry and mining. Since the founding of the state, expansion has been particularly important in chemicals, building materials, plastics, rubber products, paper and cardboard products, glass, plywood products, machinery and metals, vehicles, and mining and quarrying. Israel's chief mineral products and average annual output for the period 1959-1961 are as follows: potash, 105,000 tons; bromine, 2,400; phosphate rock, 218,000; copper, 5,600; and petroleum, 129,000.

Agriculture.—Agriculture, which employs about one sixth of the labor force, provides more than three fourths of the nation's food requirements and is also an important source of exports. Both cultivation and marketing are characterized by various forms of collective, cooperative, and private enterprise. The collective settlements (*kibbutzim* or *krutzot*, *moshavim shitufim*) form closely knit social as well as productive units. Increasingly they have been supplemented by organizations of a cooperative type, the most important of which are the workers' cooperative smallholders' settlements (*moshvei ovdim*). There are also ordinary rural villages based on private landownership (*moshavot*). Of the 750 villages of all types in 1961, 450 had been founded after the establishment of the state. The total rural population of about 500,000 occupies approximately 1,000,000 acres of cultivated land. Between 1948 and 1961 the cultivated area more than doubled, and the irrigated area quadrupled, reaching nearly 350,000 acres. Large-scale irrigation developments include the Hule project in upper Galilee, the Kishon project north of Haifa, the two large Yarkon-Negev pipelines, and the giant Jordan-Negev pipeline. Afforestation projects cover about 75,000 acres, of which 65,000 acres were planted after 1948.

The chief field crops are wheat, barley, oats, hay, and pulses. Among other farm products are milk, eggs, vegetables, potatoes, poultry, green fodder, oilseeds, tobacco, and olives. In 1955, Israel harvested its first large cotton crop, and within a few years output supplied the greater part of domestic requirements. Other industrial

crops are sugar beets, peanuts, flax, agave, and kenaf. The important citrus crop yields about 10 million cases annually for export and constitutes a major source of foreign exchange. Other fruit crops are bananas, grapes, apples, plums, and figs.

Foreign Trade.—Mass immigration and a high rate of capital construction have inevitably produced an excess of imports over exports. With the gradual growth of export industries, the deficit on the commodity account has tended to diminish steadily in relative terms, though not absolutely. Exports rose in value from \$36.9 million in 1950 to \$279.2 million in 1962, while imports increased from \$298.8 million to \$612.4 million. Hence the deficit rose from \$261.9 million in 1950 to \$333.2 million in 1962; and although the proportion of exports to imports increased from 13.5 percent to 45.6 percent in this period, the trade imbalance still represented a staggering burden. With the gains achieved by Israeli industry, industrial exports likewise rose, both in absolute terms and relative to nonindustrial exports. The country's chief exports are cut and polished diamonds, citrus fruits and citrus byproducts, textiles, eggs and other agricultural products, tires, food products, minerals, machinery and metal products, and electrical appliances. Imports include machinery and vehicles, foodstuffs, industrial raw materials, timber, and chemicals. The United States, the chief market for Israel's diamond exports, and Great Britain, an important buyer of its citrus crop, are the two major trading partners. Other trading partners of importance are countries of the European Economic Community, Turkey, Finland, and Switzerland.

Transportation and Communications.—Since the founding of the state the Mediterranean ports of Haifa and Tel Aviv have been expanded, and the port of Elath has been developed on the Gulf of 'Aqaba. Construction of a second deep-water port supplementing that at Haifa was begun in 1961 at Ashdod, about 20 miles south of Tel Aviv. Following the lifting of an Egyptian blockade, the first large vessel arrived at Elath on March 25, 1957. The merchant marine, which carries about 43 percent of the nation's imports and 31 percent of its exports, comprised 68 vessels aggregating 662,000 deadweight tons at the end of 1961.

The Israeli railroad system, comprising about 417 miles of main and branch lines (1961), connects Jerusalem, Tel Aviv, and Haifa. Main roads maintained by the government totaled 1,900 miles in 1961. Lydda (Lod), the chief airport, is an international Middle East terminus. El Al Israel Airlines, Ltd., operates services to New York and to various world capitals. Jetliner service was introduced in 1961.

Kol Israel, the state-owned radio network, broadcasts from Jerusalem and Tel Aviv in Hebrew, Arabic, and other languages. Educational television was approved by the Knesset in 1963. There are 24 daily newspapers, including 14 in Hebrew.

4. EDUCATION AND CULTURAL LIFE

Educational Facilities.—A law of 1949 provided for free and compulsory education from the age of 5 to the age of 14. Under the State Education Law of 1953, a unified state-controlled elementary school system was established, with provisions for general and religious schools, at the option of the parents. Most schools are co-educational, with eight years' study in elementary

and four in secondary schools. Secondary schooling entails a fee, but there are state subventions of fees, adjusted to the parents' income. The language of instruction is Hebrew except in the Arab schools, where it is Arabic.

The country's educational institutions accommodated approximately 600,000 students in 1961. In addition to the kindergartens, primary schools, and secondary schools, there are evening schools for working youths, schools for the handicapped, vocational and agricultural schools, schools in farm collectives, teacher-training schools, and other specialized institutions. School attendance among the Arab population in 1961 was 95 percent for boys and 50 percent for girls. Higher education is provided at Hebrew University in Jerusalem, one of the finest universities of the Middle East (enrollment, 1960-1961: 6,589); the Technion-Israel Institute of Technology (1,799) in Haifa; Tel Aviv University (825); and Bar-Ilan University (611) at Ramat Gan.

Cultural Facilities.—The continued development of Hebrew as a living tongue suitable for daily speech and modern science, scholarship, and literature is the express aim of the Hebrew Language Academy established by law in 1953. Other institutions that link the cultural life of the Israelis with the rich heritage of the Jewish people are the art museums at Jerusalem, Tel Aviv, and 'Ein Harod and several smaller historical, archaeological, and natural history museums. The Jewish National and University Library in Jerusalem is the country's largest library, with more than 1,000,000 volumes; bookmobiles cater to outlying districts. Numerous literary and technical periodicals appear in several languages.

Israel has several repertory theater companies, the best known of which is Habimah. In addition to the internationally known Israel Philharmonic Orchestra, there are a number of other ensembles, conservatories, and ballet schools.

Scientific Research.—The National Council for Research and Development in the prime minister's office provides advice on national policy and coordinates governmental activities and spending on research and development. Affiliated with it are the Negev Institute for Arid Zone Research at Beersheba, which conducts research in plant and animal biology, water desalination, and the use of the Negev's resources; the National Physical Laboratory, which establishes national standards and conducts research in the utilization of solar energy and other fields of applied physics; and the Fibers and Forest Products Institute, which conducts research on fibers, paper, and leather. The nation's Atomic Energy Commission has been occupied with a survey of the country's radioactive minerals, methods of obtaining uranium from phosphates, and means of producing heavy water. In addition, research is conducted in medicine, geology, and physics at Hebrew University; in applied mathematics, nuclear physics, and other special sciences at the internationally known Weizmann Institute of Science at Rehovot; in industrial processes by the Technion at Haifa; and in other fields by the Israel Institute for Biological Research, the Institute of Agriculture, the Geological Institute, and the Geophysical Institute.

5. GOVERNMENT

Israel has been a parliamentary democracy since the inception of the state. The literate and politically conscious electorate, though divided on many issues, is almost universally imbued with

ISRAEL: Total pop.—1965 off. est.; cities over 100,000—1963 off. est.; other pops—1961 final census. JORDAN: Total pop.—1964 U.N. est.; other pops—1961 final census.

the Zionist ideal. This has produced relative stability in leadership, which other governments of the ministerial type have often lacked. The leading political party indeed has had to depend on allied groups for a parliamentary majority, but the differences among the major parties have not been so fundamental or so bitter as to make coalition rule unobtainable. The principal domestic issues have been the degree of government control in the economy and the role of religious orthodoxy and tradition in secular matters. In foreign affairs there has been considerable opposition by leftist parties to close ties with the Western powers, and rightists have demanded greater militancy against the Arab states that surround Israel.

Governmental Structure and Political Parties.—Israel has no written constitution. The Transition Law adopted by the Knesset (Assembly) in 1949 delineated certain organic functions, such as the formation and powers of the legislative and executive branches. In 1950 the Knesset voted to legislate separately on constitutional matters, these acts eventually to comprise the nation's fundamental code of laws. The president of Israel, whose office is largely titular, is elected by the Knesset for a five-year term.

The Knesset, a unicameral, 120-member body, is elected for a four-year term by secret ballot and universal suffrage through proportional representation. The franchise is held by men and women (non-Jews as well as Jews) over 18 years of age. Voters cast their ballots for party lists rather than for individual candidates, and seats are allotted in proportion to the number of votes obtained by each list. The cabinet is responsible to the Knesset and holds office only so long as it retains the confidence of that body. The chief political parties are the Mapai (Israel Labor Party), a Zionist-Socialist party which has provided the nation's leadership since the founding of the state; the Liberal Party (formed in 1961 by a merger of the General Zionist and Progressive parties), which stresses private enterprise in the economy; the Mapam (United Workers Party) and the Achdut Ha'avoda (Unity of Labor), more leftist than the Mapai; and the ultranationalist Herut (Freedom). Smaller groups include the parties of the religious bloc and the Israel Communist Party.

Defense.—The Israel Defense Forces, well equipped and of high morale, are regarded as among the crack forces of the Middle East. A General Staff commands all three forces—land, sea, and air. Under the Defense Service Law passed in 1949 and amended in 1950 and 1952, men and unmarried women are generally drafted for military service upon reaching the age of 18. Men of the age group 18–26 serve for 30 months; of the age group 27–29, for two years. Unmarried women of the age group 18–26 also serve for two years. Men up to the age of 49 and childless women up to the age of 34 are regularly called up for service in the reserves. Army service includes a period of agricultural training, and the defense forces play an important role in education, particularly as a school for the learning of Hebrew.

Public Health and Welfare.—About two thirds of the population receive medical services through Kupat Holim, the medical branch of Histadrut, Israel's many-sided labor organization. Also important are the public hospitals and other facilities operated by the Ministry of Health; the Hadassah Medical Organization, sponsored by Hadassah, the women's Zionist organization of

America; and Malben (Institute for the Care of Handicapped Immigrants), sponsored by the American Joint Distribution Committee. Israel has the greatest number of physicians in proportion to population of any country in the world.

The National Insurance Law of 1953 provided for a comprehensive program of social insurance to come into being in three stages. The first stage (effective in 1954) comprised old-age and survivors' insurance for the entire population, maternity insurance and infant benefits, industrial accident insurance, and family allowances for each child under 14 after the third.

Public Finance.—The Israeli pound (₪) was established as the national currency in 1948, with a value of U.S.\$4.03 at the official rate of exchange. Under the succeeding systems of multiple exchange rates, however, the effective rates varied according to the nature of the transaction, while devaluations had reduced the principal rate to \$0.556 by 1953. On Feb. 9, 1962, a uniform exchange rate of ₪3 to the dollar (or ₪1 = \$0.333) was introduced.

The draft budget for the fiscal year April 1, 1963–March 31, 1964 totaled ₪2,790 million, including ₪560 million for development. Regular revenue is derived chiefly from income taxes, excises, and customs duties. Funds for development have come largely from government bond sales, foreign contributions to the Jewish Agency by fund-raising institutions such as the United Jewish Appeal, and counterpart funds of United States grants-in-aid. An important additional source was made available by a reparations agreement signed by Israel and the Federal Republic of Germany on Sept. 10, 1952 (ratified in 1953), whereby the Bonn government agreed to pay to Israel \$715 million, chiefly in German goods, over a period not exceeding 14 years.

6. HISTORY²

Internal Affairs.—Political Developments.

—Following the proclamation of the state on May 14, 1948, by the Jewish National Council, David Ben-Gurion, labor spokesman and political leader, was chosen prime minister of a provisional government, and Chaim Weizmann, leader of the world Zionist movement, was named president. The first general election was held on Jan. 25, 1949. The Mapai, a democratic labor party led by Ben-Gurion, emerged as the leading party, obtaining 46 of the 120 seats in the Knesset. The Knesset elected Dr. Weizmann president of Israel on Feb. 16, 1949, and on March 10 Ben-Gurion formed a coalition cabinet of the Mapai and most of the religious parties.

Following a succession of cabinet crises arising from economic difficulties, the second general election took place on July 30, 1951. The Mapai retained its leading position, obtaining 45 seats, but the General Zionists gained 13 seats, for a total of 20. Ben-Gurion continued as prime minister until Dec. 7, 1953, when he retired to a collective farm. On Jan. 26, 1954, Moshe Sharett, foreign minister under Ben-Gurion, headed a new coalition consisting mainly of the Mapai and the General Zionists. Meanwhile, President Weizmann had died in office on Nov. 9, 1952, and Itzhak Ben-Zvi (1884–1963), a noted Middle East scholar, succeeded as the second president on Dec.

²For an account of the events leading up to the proclamation of the state and of the warfare between Israel and the Arab states in 1948 and early 1949, see JEWISH HISTORY AND SOCIETY—16. *Zionism* and 17. *Jews in Modern Palestine*.

ISRAEL

Left: Israeli workers in the diamond-cutting industry.

Center: The Bialik School, one of the many educational institutions in Israel which receives American financial support.

Bottom: Nahalal, northern Israel, six miles west of Nazareth. This modern village, founded in 1921, on reclaimed land, was the first smallholders' cooperative settlement in Palestine. Residents live in a circular formation and tend the land strips radiating from their circle frontages.

(Left and center) Palestine Foundation Fund;
(bottom) Israel Office of Information

10, 1952. Ben-Zvi was reelected in 1957 and 1962. On May 21, 1963, Schneor Zalman Shazar was elected to succeed him as president.

Elections to the third Knesset took place on July 26, 1955, amid mounting tension between Israel and the surrounding Arab states. The Mapai suffered its first sizable loss, obtaining 40 seats. The militant Herut received 15 seats; for a gain of 7, and displaced the General Zionists as the second largest party. Ben-Gurion resumed the premiership on Nov. 3, 1955, heading a coalition of the Mapai, leftist Socialist, and smaller parties. In the fourth general election, which took place on Nov. 3, 1959, the Mapai recouped its loss, obtaining 47 seats, and the Herut won 17 seats. On December 17, Ben-Gurion formed a new Mapai-led coalition cabinet.

On Dec. 25, 1960, Pinhas Lavon, a former defense minister who had resigned under pressure in 1955, was exonerated by a cabinet committee of responsibility for a secret security venture of 1954 that had had disastrous results. The affair produced a cabinet impasse when Ben-Gurion refused to accept Lavon's exoneration and resigned on Jan. 31, 1961. With Ben-Gurion heading a caretaker cabinet, the fifth general election took place on August 15. The Mapai obtained 42 seats, for a loss of 5. The newly formed Liberal Party, headed by Nahum Goldmann, president of the World Zionist Organization, received 17 seats. Ben-Gurion again headed a new Mapai-led coalition government on November 2. He continued in office until June 6, 1963, when he resigned; on June 19, Levi Eshkol, minister of finance and a member of Mapai, succeeded to the premiership.

Economic and Social Problems.—On assuming office in 1949, Ben-Gurion had initiated an ambitious program to expand the economy and absorb the influx of immigrants. This program suffered a setback in the latter half of 1950, when the pressure of the expanding population and the rising cost of imports caused a breakdown of the price control system and a shortage of consumer goods. In February 1952, Ben-Gurion outlined a new economic policy, designed to encourage private enterprise, increase efficiency of production by competitive pricing, and curtail nonessential imports. Nevertheless, price levels continued to rise, and unemployment reached serious proportions in 1953 because of shortages of raw materials and the closing down of noncompetitive firms. Meanwhile, however, the falling off of immigration beginning in late 1951 had begun to ease pressure on prices, and gradually the new arrivals became absorbed in productive work. New and expanded enterprises began to contribute to output. By 1955 unemployment had been reduced, and output expanded by about one third over 1952.

In the next few years foreign and domestic investment mounted steadily. Irrigation projects and other long-term undertakings in agriculture, industry, and transport came to fruition. By 1958, the year of Israel's tenth anniversary as an independent state, approximately 900,000 immigrants had been absorbed, the area under cultivation had more than doubled, and over-all industrial and agricultural output had risen more than threefold. Economic conditions continued to improve in the early 1960's. Rationing had ended in 1959, the unemployment problem had been liquidated by 1962, and the general standard of living had risen appreciably since the years of austerity in the previous decade. One of the most difficult

economic problems that remained to be solved was that of the imbalance of trade. In 1962 the government introduced a far-reaching four-year plan to reduce the excess of imports, intensify development of the Negev and Galilee regions, and maintain a 10 percent average annual increase in the gross national product. By a currency devaluation on February 9, the government had sought to reduce the trade deficit by improving the competitive position of Israeli producers in world markets, and the four-year plan aimed to raise the efficiency of production, curb increases in domestic consumption so as to reduce imports, stabilize price levels, and encourage domestic saving and investment.

Among the problems of the new Jewish state has been the role of Jewish tradition in a modern community largely secular in outlook. Controversy on the issue of Jewish identity arose in 1958, when the government decreed that the designation "Jewish" should be entered on the registration cards of persons who declared themselves Jewish. Religious leaders objected that the government was seeking to usurp the right of defining who is or is not a Jew, and that this should remain within the province of the religious authorities, who have held, in accordance with tradition, that a Jew can only be someone who is born of a Jewish mother and who does not belong to another religion, or one who has been converted to Judaism in accordance with religious law. On Dec. 6, 1962, Israel's Supreme Court ruled that a Jew who becomes converted to another religion is not regarded as a Jew under the Law of Return (enacted in 1950), which recognizes the right of every Jew to settle in Israel.

Adolf Eichmann, who played a leading role in the Nazi extermination of millions of European Jews during World War II, was seized in Argentina and abducted to Israel by Israeli agents in May 1960. Eichmann was tried in Jerusalem on April 11–Aug. 14, 1961, before a tribunal of three judges, and was found guilty of crimes against the Jewish people, war crimes, and other crimes. The trial, which commanded world attention and evoked pictures of the hideous Nazi atrocities, resulted in a death sentence for the defendant, who was executed in Ramle prison on May 31, 1962.

Foreign Relations.—Israel withstood the first military threat to its independence by staving off the Arab armies in the war of 1948–1949 (see ISRAELI-ARAB WAR). Through the mediation of the United Nations, armistice agreements were signed in 1949 with Egypt (February 24), Lebanon (March 23), Jordan (April 3), and Syria (July 20). In the years that followed, however, there was neither peace nor war. The Arab states refused to accept the truce boundaries as permanent or to recognize Israel as a sovereign state. Arab leaders held that peace treaties were possible only if Israel would readmit the approximately 900,000 Arab refugees who had fled or were driven from their homes during the war of 1948–1949, and if Israel would relinquish all territory not included in the United Nations partition resolution of 1947. Israeli leaders declared that the actions of the Arab states themselves (in the invasions of 1948) had nullified the United Nations partition resolution, and that the conditions for peace put forward by the Arab leaders would mean the death of Israel as a nation. In the consequent impasse over a permanent settlement, Arab governments mounted economic boycotts

against Israel, Israeli-bound shipping was blocked by Egypt in the Suez Canal and the Strait of Tiran (at the entrance of the Gulf of 'Aqaba), and Arab propagandists spread hatred of Israel.

A major source of Israeli-Arab tension was the continuing border violence in the form of Arab raids on Israeli settlements and Israeli retaliatory attacks. The chief areas of conflict were the northeastern border with Syria, the Sea of Galilee, the eastern border with Jordan (including divided Jerusalem), and the outlying Negev areas facing the Egyptian-held Gaza Strip. Although the United Nations truce staff was able to halt sustained actions by the armed forces of the respective sides, it proved almost powerless to prevent incessant forays by small Arab marauder bands. According to Israel, in the period 1951-1955 Arab attackers exacted a toll of almost 900 Israeli dead and wounded.

As border violence mounted in intensity, Israel watched apprehensively while Egyptian military power was increased by Communist-bloc deliveries (beginning in late 1955) of jet planes, tanks, and other modern weapons, and as Egyptian President Gamal Abdel Nasser took steps in 1956 to organize an anti-Israeli military alliance among the Arab states. On Oct. 29, 1956, Israeli Army columns struck across the southern border at Egyptian positions in the Sinai Peninsula, where Egypt had staged many of the *fedayeen* (commando) raids against Negev settlements. In a few sharp battles, chiefly at El Arish (Al 'Arish), Abu 'Aweigila, and Rafa (October 30-November 1), the larger and better-equipped Egyptian forces were routed, and the Israelis gained control of the Sinai area and the Gaza Strip. A United Nations-sponsored cease-fire came into effect on November 6, and Israeli forces soon proceeded to withdraw from Egyptian territory. Israel completed its withdrawal on March 8, 1957, with the evacuation of the Gaza Strip and the Sharm el Sheikh section of southern Sinai. Units of the United Nations Emergency Force took over Sharm el Sheikh and were stationed along the Gaza frontier to prevent border incidents.

In the years immediately following the Sinai campaign, border violence diminished, and Israeli ships passed unmolested through the Strait of Tiran. With the growing power of Nasser, however, prospects of an Arab-Israeli peace seemed as distant as ever, and the Israeli government continued to stress vigilance and to seek arms aid from the West. Nasser revived a long-standing issue regarding Israel's use of the Suez Canal in 1959, when he began to subject to cargo seizure and other forms of harassment non-Israeli ships carrying nonmilitary cargoes to and from Israel by way of the canal. In 1960 and 1961, Ben-Gurion visited Washington, London, and Paris, conferring with the heads of government in an effort to obtain big-power backing for a Middle East settlement and an end to the arms race in the region.

ISRAEL, Tribes of. Traditionally, the 12 Hebrew tribes were the descendants of the 12 sons of Jacob. The names of these sons—(by Leah) Reuben, Simeon, Levi, Judah, Issachar, Zebulun; (by Rachel) Joseph, Benjamin; (by Bilhah) Dan, Naphtali; (by Zilpah) Gad, Asher—are found, for example, in Genesis 35:22-26, and the list of their offspring, the Hebrew forefathers, is given in Genesis 46:8-27. The allotment of Canaan, after its conquest by Joshua (c. 1250-1200 B.C.), is described in Joshua 13-19; the account is traditional and somewhat idealized.

The conquest was not a sudden irruption of nomads from the desert, but a slow and steady infiltration, following an initial invasion, into the fertile valleys and open country, and leading finally to the capture of the Canaanite cities. The narratives of the Old Testament tell us nothing of the conquest of central Palestine, where the two small "Joseph" tribes, Ephraim and Manasseh, were found later; presumably they had been settled there from an early time, possibly even before the conquest under Joshua.

Entering the land at a point just north of the Dead Sea, the Hebrew advance was blocked by the old Canaanite stronghold of Jericho. Its capture is the theme of the thrilling story in Joshua 6. The adjacent territory later was allotted to the tribe of Benjamin, and that which lay to the west of this, toward the Mediterranean Sea, belonged to Dan; later on, under Philistine pressure, this tribe moved to the far northern end of Palestine. Everything south of this central belt belonged to Judah and Simeon. North of the tribe of Manasseh lay the regions of Asher, Zebulun, Naphtali, and Issachar—territory known after the Babylonian exile (perhaps from 400 B.C.) as Galilee. On the east side of the Jordan River, in addition to the "half tribe" of Manasseh, lay the territories of Gad and Reuben. The characteristics, and to some extent the location, of the tribes are given in the ancient ballad in Genesis 49, *The Blessing of Jacob*. Only Levi was allotted no tribal territory; as the priestly tribe, it was given cities scattered among the 11 others (Joshua 21).

Following the death of King Solomon in 922 B.C., the 10 northern tribes revolted and formed a separate kingdom, the Kingdom of Israel, leaving the tribes of Judah and Benjamin as the Kingdom of Judah, a landlocked realm in the southern highlands. When Israel was conquered by the Assyrians in 721 B.C., the leaders of the people and the well-to-do were led into exile (Sargon II recorded their number as 27,290); in their place were settled eastern peoples from Elam, Babylonia, and Syria. When Judah fell before Nebuchadnezzar II in 597 B.C., and again, after an attempted revolt, in 587, the Judeans were decimated; only the poor were left behind to till the soil and eke out a miserable existence. The northern exiles were never heard from again; they became the Ten Lost Tribes of much later speculation and legend, some identifying them with the Tatars, or the Chinese, or even the American Indians. The truth is that they were probably completely absorbed by the people among whom they were scattered—less than 30,000 persons would soon melt into the vast population of the East. After the Babylonian exile, when a fresh begin-

ning was made in Judah (Judea), the tribal divisions were never again of territorial significance, but only of genealogical interest.

ISRAELI-ARAB WAR, a conflict fought between the new state of Israel and its Arab neighbors in 1948-1949. The basic causes of the war were (1) the Jewish resolve to create a Jewish state in Palestine where European survivors of the Nazi massacres could find a new life; (2) the Arab resolve to resist what Arabs saw as a foreign invasion of a Arab homeland; and (3) the withdrawal of the British from Palestine, leaving the Jews and the Arabs to fight it out. Emotional tides on both sides ran deep and strong. The Jewish cause was stoutly supported by the American and European Jewish communities, while the Arab cause was championed by all the Arab nations of the Middle East.

Preliminary Operations.—Sporadic fighting, partly of a guerrilla nature, began shortly after Nov. 29, 1947, when the United Nations General Assembly passed a resolution providing for the partition of Palestine into an Arab and a Jewish state. The Arab forces consisted of volunteers from Syria and Iraq, composing the Army of Arab Liberation, and of Palestinian guerrillas under the Arab Higher Committee. The military forces of the Jewish community had been built up clandestinely over a considerable period under the name of Haganah (defense force). They included a mobile striking force, called Palmach (spearhead), of about 3,000 soldiers; field troops, distributed territorially in six brigades, numbering about 12,000 or 15,000; and local defense forces, comprising the remaining able-bodied Jewish population for whom any kind of weapons could be provided, totaling about 32,000. Armament was of a wide variety; there were approximately 10,000 rifles, fewer than 1,000 machine guns and automatic weapons of all kinds, several hundred mortars, virtually no artillery, no tanks, and no military aircraft. Organization, however, was excellent; military training, directed largely by Jewish officers who had served with the British Army in World War II, attained a high level of efficiency, while the spirit and determination of the Haganah left nothing to be desired.

The most serious problem for the Haganah was the supply of the 100,000 Jewish inhabitants of Jerusalem, which was surrounded by Arab-held territory. Very heavy fighting attended attempts (usually successful) to push supply convoys through to Jerusalem, but the road rarely remained open for more than two or three days at a time. In April 1948, the Army of Arab Liberation was decisively defeated at Mishmar ha Emeq (Mishmar Haemek), followed by the fall of Tiberias (April 18) and Safad (Safed; May 10) and by the surrender of Jaffa (May 13). The important port city of Haifa was taken over by the Israelis during the last week of April.

Invasion by the Arab States.—The British mandate ended on May 14, 1948, concurrently with

the declaration of the independence of the state of Israel. On the following day, the armies of Egypt, Transjordan, Iraq, Syria, and Lebanon entered the struggle. The Syrians gained initial successes in the northeast, but their net accomplishment for the entire war consisted in holding a bridgehead on the west bank of the Jordan River. In the center, the Arab Legion of Transjordan—by far the most effective of the Arab invading armies—quickly took possession of the Old City of Jerusalem (May 18) and advanced to Latrun, on the main road between Jerusalem and Tel Aviv. In the south, the Egyptian Army advanced into the Negev, occupied Gaza (May 16) and Beersheba (May 20), and besieged a number of fortified Jewish settlements with little success. Iraq sent a modest force, which took over Arab-inhabited territory north of Jerusalem. Egyptian and Syrian aircraft carried out sporadic raids that accomplished little.

The Israeli forces were at first occupied chiefly with holding their own, pushing through a new road to connect Jerusalem with the coast, and—with the ending of the British naval blockade—importing with desperate haste weapons of all sorts and from many diverse sources. Effective June 11, the United Nations succeeded in imposing a four-week truce, a period which the Israelis used for reorganization and training.

Israeli Offensives.—Fighting was resumed on July 9, after both sides had rejected the peace proposals of the United Nations mediator, Count Folke Bernadotte (q.v.). A major Israeli offensive, involving three brigades and parts of two others, was launched on the central front. It quickly overran the Arab Legion's forward positions at Ramle and Lydda (Lod), captured the important Lydda Airport, regrouped, and was preparing for a new assault on Latrun when a second truce came into force on July 18. In the north, the Israelis cleared the entire belt of southern Galilee from Haifa to the Sea of Galilee, and captured Nazareth (July 18). This was a remarkable accomplishment for a new army. It gave the Israelis possession of the most important communications centers of Palestine, and seemed to have convinced King Abdullah of Transjordan that he should not take further military risks. For the remainder of the war the Arab Legion fought on the defensive.

The Egyptian Army in the south became the focus of Israeli concern. In a brilliant series of offensive operations (October 15-22; December 23-January 7), the Israelis pinned the Egyptian forces against the Mediterranean Sea, cut them off from their main advance base at El Arish (Al 'Arish), and was faced with the choice of surrender or destruction when, on Jan. 7, 1949, the Egyptian government declared to Dr. Ralph J. Bunche (q.v.), who had succeeded Count Bernadotte as United Nations mediator, its readiness to negotiate an armistice. Armistice agreements were signed with Egypt on February 24, Lebanon on March 23, Transjordan (later Jordan) on April 3, and Syria on July 20. No armistice, however, was concluded between Israel and Iraq or Saudi Arabia.

Results of the War.—Victorious against all the invading armies, Israel was able to insist on armistice terms that left the new state in possession of considerably larger areas of Palestine than had been allotted to it by the United Nations partition resolution. Among these areas were western Galilee, the Jaffa enclave, and an expanded corridor to the New City of Jerusalem, together with the New City itself. From the half-armed

embryo that began the war, the Israeli Army had become composed of 12 strong infantry brigades, supported by tanks and artillery, as well as by an air force and navy with reasonably modern if somewhat diverse armament. Superior leadership and organization were among the ingredients of victory, but at bottom Israel's success must be attributed to the remarkable spirit of its soldiers, who fought with disciplined dash, devotion, and self-sacrifice, which the Arabs—many of whom fought bravely enough—could no more withstand than they could develop the organizational means to coordinate and unify their efforts.

GEORGE FIELDING ELIOT,
author of "*The Ramparts We Watch*" and "*Victory Without War*."

ISRAELITES, iz'ri-él-it-z, an alternative rendering in English of the Hebrew term *Bene Yisrael*, whose literal translation is "sons of Israel" or "children of Israel." The Israelites comprised 12 tribes, each of which traced its ancestry to one of the 12 sons of Jacob, who was also called Israel (Genesis 32:28). For the entire period of slavery in Egypt, wandering in the desert of Sinai, the conquest of Canaan, the fighting under the Judges, and the establishment of a united kingdom under Saul, David, and Solomon, the terms "Israelites" and "Hebrews" can be used interchangeably. After the death of Solomon, however, the kingdom was split into two: Israel, the northern kingdom, whose inhabitants were called sons of Israel, house of Israel, or Israelites; and Judah, the southern kingdom, whose people were called sons of Judah, men of Judah, or Judaeans (from which the English term "Jew" is derived). When the Kingdom of Israel was conquered by Assyria in 721 B.C., its people, many of whom were led into captivity, ceased to exist as an ethnic entity. The term "Israelites" can therefore be applied to all the Hebrews up to the death of Solomon, and thereafter to the inhabitants of the Kingdom of Israel until the Assyrian captivity, following which the historical survivors of the 12 tribes should be referred to as Judaeans or Jews.

RAPHAEL PATAI.

ISRAËLS, iz'ra-ëls, Jozef, Dutch painter and etcher: b. Groningen, Netherlands, Jan. 27, 1824; d. The Hague, Aug. 12, 1911. He studied under such diverse masters as Ary Scheffer and Paul Delaroche. Until 1857 he worked insignificantly as a concocter of historical pastiche. Turning to the lives of humble people, he attracted the notice, some years later, of Théophile Gautier, a shrewd critic, who gave him unstinted praise. Israëls has been called an imitator of Jean François Millet, but his narrative gift, though less dramatic than Millet's, is perhaps more consistently clear. Moreover, until his appearance, Dutch art had been smothered by a routine respect for the past. Primarily a genre painter, Israëls nevertheless in-

spired a whole school of gifted landscape artists, among them Anton Mauve.

WALLACE BROCKWAY.

ISSACHAR, is'â-kâr, in Biblical history, the ninth son of Jacob and the fifth by Leah, and the eponym of one of the tribes of Israel (see ISRAEL, TRIBES OF). Tola, a minor judge (Judges 10:1), and Baasha, a king of Israel (I Kings 15:27), were of the tribe of Issachar.

ISSUE, ish'ü, in law, the descendants of a common ancestor, or in pleading, a point affirmed by one party in a suit and denied by the other. In the latter sense an *actual issue* is one formed in an action regularly brought to try a question of right; a *collateral issue* is one formed in a matter only indirectly in the line of the pleading; a *feigned issue* is one formed in a fictitious action, under the authority of a court, to try a question of fact before a jury; a *formal issue* is one formed according to the rules required by law; a *general issue* denies the whole declaration in direct terms; an *immaterial issue* is formed on some nonessential matter that will not determine the merits of the cause; an *informal issue* arises when a material allegation is improperly traversed; a *material issue* determines the merits of the cause when decided; a *special issue* is a single point selected by the defendant on which he rests his whole cause; and a *common issue* is one formed on the plea of *non est factum* to an action of covenant broken.

ISSUS, is'üs, ancient town, Asia Minor, in the Province of Cilicia, situated five miles northwest of modern Dörtöyl, Turkey, on the Gulf of İskenderun, in a narrow coastal plain to the south of passes through the Taurus Mountains. Apart from its importance to ancient geographers as the most easterly point of the Mediterranean Sea in reckoning distances westward, Issus was the scene of two ancient battles.

(1) In 333 B.C., on his eastward march of conquest, Alexander the Great, with probably 35,000 troops, routed Darius III, king of Persia, who had more than 100,000 soldiers. The Battle of Issus ended ancient Asian power in the Mediterranean area.

(2) In 194 A.D., the Roman emperor Lucius Septimius Severus defeated his rival Gaius Pescennius Niger Justus and thus secured his throne. Some 20,000 of Pescennius Niger's soldiers are said to have fallen on the field.

P. R. COLEMAN-NORTON.

ISSY-LES-MOULINEAUX, ê-sê'lâ-môô-lê-nô, town, France, situated in the Department of the Seine, 4 miles southwest of the Cathedral of Notre-Dame, Paris. An industrial suburb, it produces aircraft, steel pipe, electrical equipment, cigarettes, and chemical pharmaceutical products. It is a port on the Seine River and also serves as a heliport for Paris. Pop. (1962) commune, 52,335; town, 51,440.

ISSYK-KUL, is'ik-kûl', lake, USSR, situated in the Kirghiz Soviet Socialist Republic between the Kungei Ala-Tau range to the north and the Terskei Ala-Tau range to the south. It has an area of 2,395 square miles. Its shore is a tourist region dotted with health resorts. Grain is grown in the basin of the lake, and there are fisheries at Rybachye at its western end.

ISTANBUL, *ış-tām-bōōl'*; Turk. *ê-stām-bōōl'*, Turkey (corrupted from Gr. *eis tēn polin*, "to the city"); usual European form, STAMBOUL; formerly CONSTANTINOPLE (q.v.); anciently BYZANTIUM (q.v.). Principal city of the Republic of Turkey and capital of the vilayet (province) of Istanbul, it was previously capital of the Ottoman empire. The Ottoman Turkish names were Qostantiniyeh (city of Constantine) and Dersaadet (Abode of Felicity); the present name, informally used for more than a century, was officially adopted in 1930. The population (census of 1945) of the city proper is 860,558, and of the vilayet (provisional 1950), 1,179,666. The city, partly in Asia and partly in Europe, is built around the exit of the Bosphorus into the Marmara (Marmora) Sea; latitude 41° 0' 16" N., longitude 28° 59' 14" E. The European portion is deeply indented by the Golden Horn (Turk. *Haliç**; Gr. *Keraton*), an inlet extending inland from the southern terminus of the Bosphorus for some six miles, curving clockwise to the northwest and forming a remarkably secure and commodious harbor. On the shore of the Bosphorus, north of the Golden Horn's entrance, are also deepwater docks, where the largest vessels can be berthed.

Istanbul comprises three principal divisions: (1) old Istanbul; (2) Galata-Beyoğlu; and (3) the quarters on the Asiatic shore. Each of these divisions is subdivided into numerous quarters, each with its distinctive name and many with distinctive populations, some largely Turkish, others largely Greek or Armenian or Jewish. In these, Istanbul, in contrast to the homogeneous nature of the rest of modern Turkey's population, continues to represent the heterogeneous population formerly characteristic of the Ottoman Empire, of which it was the capital until 1923.

Old Istanbul.—On the European shore between the Golden Horn and the Marmara lies Istanbul proper, in the limited sense of the name, the Turkish city converted after 1453 from the Greek Constantinople into which Constantine the Great had transformed in 330 the Roman-controlled Greek city-state of Byzantium. This is the area which in ancient and medieval times was surrounded by the walls whose famous remains—after 26 sieges and 44 earthquakes—are one of modern Istanbul's principal sights. The sea walls, which extended along the European coast of the Marmara from the fortress of Yedi Kule (Seven Towers, Byzantine Golden Gate) northeastward to Sarayburnu (Palace Point, Seraglio Point) and thence northwestward along the southern shore of the Golden Horn to Eyüp, are largely destroyed; but the land walls (Eyüp to Yedi Kule), which formed the third side of the triangle, are in a remarkable state of preservation.

Galata-Beyoğlu.—The regions on the European shores northeast of the Golden Horn form the second main division of the city. They include Galata, the quarter immediately skirting the shore, and above and behind it Beyoğlu (Gr. Pera) as well as many other built-up quarters along and above the Golden Horn and the Bosphorus. Continuously from Byzantine times Galata-Beyoğlu have been cosmopolitan, polygot centers and have set the nonnational Levantine tone which travelers often wrongly regard as characteristic of the entire city. In fact, old Istanbul, the city's major division, is largely

Turkish and was largely Greek until 1453. Cosmopolitan Galata-Beyoğlu include the most modern and westernized parts of the city. They contain the principal stores and hotels, and they form the commercial center of the entire city as well as the winter residential center of the modern city.

Asiatic Shore.—The third major division of modern Istanbul is the metropolitan area on the Asiatic shore, across from the mouth of the Golden Horn, and principally comprising the regions of Üsküdar (Scutari), Haydarpaşa (Haydar Pasha), and Kadıköy (Chalcedon).

Other Areas.—In addition to the three major areas there are many villages and towns, some quite sizable, which stretch in a virtually unbroken series along both shores of the Bosphorus northward almost to the Black Sea, and also the increasingly important residential and industrial areas along the Marmara's European shore westward from Yedi Kule and along its Asiatic shore eastward from Kadıköy. Finally, opposite this Asiatic shore and some five miles into the Marmara from the center of the city (the mouth of the Golden Horn) are the idyllic Princes Islands, traditionally named from their role as a seat of exile for royalty in Byzantine times (395-1453). Of these islands (*adalar*), four today are inhabited in significant numbers. These range in size from Büyük Ada (Great Isle, Gr. Prinkipo), through Heybeli Ada and Burgaz Ada down to Kınalı Ada (Gr. Prōti). In addition to their permanent populations, the islands, as important resorts, attract numerous summer residents and visitors.

Topography, Communications, Climate.—Almost the entire metropolitan area, including suburbs, is extremely hilly. The attempt to demonstrate that old Constantinople, the "New Rome," was built like its prototype upon seven hills is not convincing, but there are few regions in the city where a commanding eminence does not offer a view over steep hills and shining waterways. The somber colors of unpainted wood houses and of coral tile roofs are everywhere broken by clumps of trees, the cypress being especially prevalent.

Communication and transportation between the several regions of Istanbul are complicated by the rugged terrain, the many waterways, and the fact that all except the few new or recently burned-over and rebuilt sections of the city are characterized by very narrow and crooked cobblestone streets. Two bridges span the Golden Horn. At its mouth is the Galata Bridge, a floating structure which can be opened to permit the passage of ships. This bridge carries from Galata to Yeni Cami (the New Mosque quarter of old Istanbul) all tram traffic crossing the Golden Horn. Further up that inlet is the newer Atatürk Bridge. Old Istanbul and Galata-Beyoğlu have adequate tram systems, the latter including a line along the European shore of the Bosphorus past the village of Arnavutköy, location of the Istanbul American College for Girls, to Bebek, the seat of Robert College (q.v.), the American men's college. A tram system also operates in the Üsküdar-Kadıköy area. In addition, major streets have evolved into fair motor roads, and bus service greatly eases problems of communication. There is, however, no bridge across the Bosphorus. Consequently ferries remain as indispensable as they are characteristic of Istanbul life. One line travels the Golden

* In Turkish, *ç* is pronounced *ch*. Where subsequently used in text, *c* is pronounced as *j*, and *ç* as *sh*.

Horn from the Galata Bridge to Eyüp. Others from the same terminus serve both shores of the Bosphorus, and the Princes Islands. There are also motor vehicle ferries at main points and a railroad car ferry from the Sirkeci Station (in old Istanbul), terminus of the railroad from Edirne and European points, to Haydarpaşa, the railroad on the Asiatic shore of the Baghdad line. West of the walls at some distance along the Marmara shore is the Yeşilköy Airfield served regularly by several major international lines and one of the Middle East's principal landing fields. Here are also located large installations of the Turkish State Airways, which link Istanbul with the rest of the country.

The climate is temperate and continental. Summers are warm but dry and not excessively hot, the surrounding seas not only tempering the heat but also making much of the city itself a summer resort and bathing beach. Winters are cold and damp, December to February constituting the rainy season. Snows are not unusual, although they seldom last long. The beauty of Istanbul and its gardens in spring, summer, and fall has been celebrated by the many writers whom this cosmopolitan center between Europe and Asia has attracted over a period of centuries. Likewise well known are its excellent fruits and vegetables and the fish from the Bosphorus fishing grounds.

Museums and Monuments.—Objects relating to the long and important past of Istanbul and of the provinces governed therefrom have been gathered into the city's uniquely rich museums. The most important are those comprised in the museum-complex of Top Kapu Sarayı (the Grand Seraglio, palace of the Ottoman sultans until the 19th century) on the point of land separating the Golden Horn from the Marmara. These include: (1) the archaeological museums and collections, rich in objects from Anatolia and Palestine-Syria, the great showpiece being the *Sarcophagus of Alexander*; and (2) the Islamic and particularly the Ottoman collections, most notable being the Ottoman rulers' vast living quarters (entirely restored and largely furnished with objects of the times), the Ottoman sultans' treasury and collection of Chinese ceramics, and an unrivaled collection of Moslem implements of war. In addition to the vast Top Kapu Sarayı collections, mention should be made also of the Evkaf Museum near the Süleymaniye Camii (Mosque of Sultan Süleyman the Magnificent) in old Istanbul, another collection of notable creations of Ottoman and Moslem art. St. Sophia (Aya Sofya; see SAINT SOPHIA), the last great gift of Greek genius, the most magnificent architectural monument of the Greek Orthodox world, and for centuries one of the chief mosques of Turkish Istanbul, has been converted by the Turkish Republic into a museum. Aside from the structure itself, it is particularly noteworthy for its Byzantine mosaics which, covered with plaster by the conquering Turks (1453), were uncovered and restored after the foundation of the Turkish Republic (1923).

Apart from Aya Sofya and the great walls, the other remaining Byzantine monuments of Istanbul are of importance chiefly to the specialist. Many were converted by the Ottomans to their own uses. Of those left unchanged the most spectacular are the vast underground cisterns, which still form part of Istanbul's water system. Modern Greek churches in the city are

of no special architectural interest, and there are no outstanding Armenian or Jewish edifices. Nor are the monuments of Galata-Beyoğlu of great architectural interest, except possibly the Tower of Galata, dating from 474-491, which has been used in modern times as a fire lookout.

Ottoman monuments, many of them historically important, are numerous. Chief among them are the imperial mosques, erected by the principal sultans as burial places for themselves and their families. Of a distinctive style, their domes and minarets, crowning many of Istanbul's hills, give the city its renowned skyline. The principal Ottoman imperial mosques include those of Mehmed (Mohammed) II, the Conqueror; Bayezid (Bajazet) II; Süleyman (Suleiman) the Magnificent; Selim I; Ahmed I; and the Yeni Cami (New Mosque), each the center of a quarter bearing its name. Attached to the mosque-complexes are small and circular *turbehs*, in whose floors are the graves of the sultans, their families, and their close associates, while other graves are found around the mosques. Other famous men are buried near fountains, schools, libraries, or other foundations which they established as "good works," not infrequently along the public thoroughfares. This is particularly true of Divan Yolu (the Divan Street), which stretches from Aya Sofya to the Mosque of Bayezid II and which with Ankara Caddesi, formerly Bab-ı Ali Caddesi (Sublime Porte Street), now the principal book market of the city, forms the main artery of old Istanbul.

Other important Ottoman monuments include the twin fortresses of Anadolu Hisar (Castle of Asia) and Rumeli Hisar (Castle of Europe), built on the shores of the Bosphorus near that strait's narrowest part. These were erected before the fall of the city proper into Turkish hands. Of 19th century royal palaces the most important are: (1) that of Dolmabahçe on the Bosphorus shore at Beşiktaş, a principal landmark of the waterfront and frequently used as the residence of the Turkish president when he is in Istanbul; (2) Yıldız Sarayı, a palace-complex atop the hills farther up the Bosphorus and well known as the home of the recluse Sultan, Abdül-Hamid II; and (3) Beylerbeyi on the Asiatic shore.

Quarters of the City.—No section of Istanbul is more famous than that of its bazaars, the great Kapalı Çarşı (covered market) which stands on the slopes of old Istanbul looking down on the Golden Horn. Down from it stretches the principal open market of the city (the Mahmud Paşa Çarşısı). The covered bazaar includes miles of roofed and cobblestoned passages lined with tiny shops. The entire building can be locked at night. Its center is the Bedesten (Bezestan), or principal strong room and depot, formerly a depository of the most valuable wares. With the westernization of the city under the republic, the bazaars have lost some of their color, but their importance as the people's market place continues unabated.

At the head of the Golden Horn and beyond the city's mainland walls lies the quarter of Eyüp, in old-fashioned Moslem eyes the most sacred section of the city, owing to the location there of the mosque and supposed tomb of a companion of the Prophet Mohammed. It is held that the site of the tomb was miraculously revealed to the Ottomans during the siege of the city (1453). Since that date the site has been venerated, and

Below: The Blue Mosque, or Sultan Ahmed Mosque (17th century), is one of the architectural treasures of Istanbul. It takes its name from the blue tiles that adorn its interior.

until the 20th century it was closed to most Christians. It was the scene of ceremonies at the accession of a new sultan, and around it were created what are historically the most important cemeteries of the Ottoman capital. The vast burial grounds of Üsküdar are, however, far more picturesque. Early in the 20th century the importance of Eyüp began to decline, but it remains in many respects the most Ottoman and one of the most interesting quarters of Istanbul.

Libraries and Education.—During the centuries of Ottoman history, and especially as a result of conquests in Arab lands and in Persia (Iran), Istanbul gradually became and still remains the world's most important depository of Moslem manuscripts. These manuscripts, many of them unique and in a scientific sense priceless, were largely housed in small private libraries erected by individuals. Imperial collections also contained valuable items. The twin tasks of cataloguing and of providing centralized housing for this mass of material, as well as that of cataloguing and systematizing the great mass of official documents left from Ottoman times, have made increasing progress since about 1850, but still remain far from completed.

Centers of interest in the modern city include Istanbul University (q.v.), a large complex of buildings on the site of the Ottoman Ministry of War, housing Turkey's largest center of higher learning. A stately fire tower near the main building is the university's landmark. This tower, with its companion in Galata, remind one that fire, together with not infrequent earthquakes, is still the chief fear of the largely wooden-built city. Until the installation of motorized fire-fighting equipment, conflagrations frequently devastated large sections of the city. With the establishment of the republic (1923), however, the picturesque volunteer fire brigades disappeared as well as the once famous packs of street scavenger dogs, which formerly attracted the attention of all newcomers.

In addition to the university and the Superior Engineering School (near the newer Galata-Beyoğlu section), Istanbul contains numerous other institutions of higher learning, as well as adequate secondary and elementary schools, and is the center of education for the entire nation. In this respect Ankara has only partly supplanted the former capital.

Hospitals and Parks.—A number of good new hospitals, including the Admiral Bristol Hospital (an American Protestant Mission enterprise named for the American high commissioner to Turkey during the post-World War I years) also distinguish the city. Istanbul's several parks, many of them enclosing historic sites or designed to provide vistas leading to such sites, add to its attractiveness. The city also contains the modern İnönü Stadium, center of the football (soccer) matches which are Turkey's leading sports.

Industries.—Istanbul is not a large industrial center, but its tobacco processing plants, glass and shoe factories, gas and electric works, oil company installations, and the many and varied small industries and craftsmen's shops which it contains constitute an important component in Turkey's national economy. The city is the republic's major port of entry—that of export being Izmir (Smyrna)—and the customs houses and harbor works, as well as the shipyards, are vital in the city's and the nation's commerce. Istanbul is also Turkey's financial center.

With the creation of the Turkish Republic, many Stamboules (regular term for citizens of the city) felt that their city was being neglected in favor of the new construction undertaken at Ankara and elsewhere in Anatolia, that Istanbul was being heavily taxed—not in its own interest but to pay for developments in other regions of Turkey—and that it was not receiving a fair share of the new industrial plant which the republic, under its state socialist (*étatist*) program of westernization, was installing in the country. Subsequently these apprehensions were proved partly unjustified and much modernization was undertaken in the city. Nevertheless it remains true that in some respects Istanbul is as much a city of the past as of the present, that it continues more to typify the late Ottoman Empire than the modern Turkish Republic, and that the population of the city, or at least the non-Turkish sections of it, is not in wholehearted sympathy with all of the reforms characteristic of the new Turkey. On the other hand, it must be remembered also that in the late 19th and early 20th centuries Istanbul was the cradle and the principal center of nascent Turkish nationalism (see also *TURKEY—History*) and that it then was and subsequently has remained the center of the Turkish press (daily, periodical, and book), the professions, and the arts. Thus, on the basis of many considerations more important than its size (almost one in every 20 of Turkey's citizens lives in Istanbul), its influence over the rest of Turkey has persisted despite the shift of the capital to Ankara; and Istanbul is still unquestionably modern Turkey's most important city.

History.—Istanbul's uniquely strategic location gives it command of the Bosphorus, a major link in the only sea route from the Black Sea to the Mediterranean. The narrowest point of the Bosphorus, lying within the city limits, is little more than half a mile wide. At the same time, since Istanbul also stands at the easiest crossing between the land routes which descend through the Balkans from central and western Europe on the one hand, and those routes which come from Asia proper through Anatolia (Asia Minor, "Turkey in Asia") on the other hand, the city—together with the general straits area or Marmara region—is as strategically located with respect to land-borne travel and commerce as to that which goes by sea. In consequence Istanbul, which has been traditionally the center of government, commerce, finance, and intellectual activity for the entire Black Sea-Aegean-Balkan-Anatolian area, more than once and for long periods has vindicated her claims to be the naturally endowed seat of the capital of world empire.

The city's history falls into four periods:

(1) Ancient, classical, pre-Christian times—the period of old Byzantium (q.v.).

(2) Byzantine-Christian times, from the re-foundation of the city by Constantine the Great (330) as Constantinople (q.v.) or "New Rome," capital henceforth of the Eastern Roman Empire which eventually became the Orthodox (Greek Christian) state and city and which survived despite all vicissitudes until its capture by the Ottomans in 1453.

(3) Ottoman-Turkish period (1453–1923), during which the city ceased to serve as Christendom's principal bulwark against Islam, but instead became the seat of the last great Moslem world state and the center of Islam's latest and greatest threat to European Christendom.

(4) The most recent period—that of the Turkish republic (after 1923). The Turkish nation discarded much of its previously cherished Moslem tradition, as well as the Levantine type of government and life that had marked the later Ottoman period, and embarked on a course of nationalism and Westernization that entailed the erection of new Ankara in the heart of Anatolia as the modern national capital of new Turkey. Under the republic, Istanbul was reduced to the rank of a provincial capital still overshadowed by its own past glories and characterized, as the rest of new Turkey was not, by sizable non-Moslem and non-Turkish minorities who kept alive some of the Ottoman past that was largely abandoned elsewhere in Turkey.

LEWIS V. THOMAS

*Late Professor, Department of Oriental Studies
Princeton University*

ISTANBUL UNIVERSITY, in Istanbul, Turkey, is the oldest and largest university in the country. It is secular, coeducational, and state supported. Like the other Turkish universities, it is guaranteed administrative and academic independence and financial autonomy by the university law of 1946.

The university was founded in 1453, although its history can be traced to ancient times. It underwent many reorganizations, notably in 1896, and between 1923 and 1933. Since 1948, it has comprised six faculties: arts and letters, economics, law, medicine, science, and forestry. In addition, there are schools of dentistry, pharmacy, and foreign languages, and institutes of journalism and economic development. In the 1960's enrollment was approximately 25,000 annually, and the staff exceeded 1,000. The central library housed about 200,000 volumes.

Affiliated with Istanbul University is the Technical University of Istanbul (founded 1883). Civil, mechanical, electrical, and mining engineering, and architecture are the principal subjects. Enrollment in the 1960's exceeded 2,500, and the staff numbered approximately 250. There were more than 50,000 books in the library.

History. Istanbul University is one of the oldest universities in the world. Its roots were already in existence when Constantine I refounded Byzantium as Constantinople in 330 A.D. In 423, Theodosius II reorganized the university, then known as the University of Constantinople, by appointing 31 state-paid professors. By the 500's its faculty of law was comparable to those of Rome and Berytus (Beirut), and by the late 800's the university was a world center for the humanities and philosophy. Under Constantine VII (reigned 913–959) additional chairs of philosophy, geometry, astronomy, and rhetoric were founded, and instruction was being given in arithmetic, music, grammar, law, and medicine. After a brief decline, Constantine IX (reigned 1042–1055) reestablished the university with schools of law and philosophy. However, by 1204

it had again degenerated, and it was moved to Nicaea. It was revived in Constantinople in the late 1200's, but with the decline of the Byzantine empire, the university lost its position as a prominent seat of learning.

On the establishment of the Ottoman empire in 1453, Mohammed II revived the university as the Turkish University of Constantinople. Between 1470 and 1475, 16 new colleges were added. In 1555, Suleiman I further expanded the university and made it one of the largest and most progressive of its age. The decline of the Ottoman empire in the 1800's was reflected in the failing fortunes of the university. Theology became the principal subject, and advances in sciences and general education were largely ignored. However, Selim III (reigned 1789–1807) founded an engineering school, which later became the Technical University of Istanbul, and Mahmud II (reigned 1808–1839) established a faculty of medicine. Then a new organization, the Ottoman University of Istanbul, was founded in 1870. Modeled after contemporary European universities, it included departments of law, philosophy, literature, natural science, and mathematics. The university declined in the next decade, and the medical and law schools functioned autonomously.

The modern University of Istanbul dates from 1896, when Abdul-Hamid II completely reorganized the old faculties. By the early 1900's, departments of theology, mathematics, and literature were operating successfully. The faculties of medicine and law were brought into the university. When the Republic of Turkey was founded in 1923, the university received a fresh impetus. It was provided with funds from the state budget, placed under the jurisdiction of the ministry of education, and completely divorced from its previous religious affiliations. A general modernization took place in 1933, when many new buildings and laboratories were added.

ISTHMIAN GAMES, is'mē-ən gāmz, were a festival of ancient Greece, celebrated on the Isthmus of Corinth, in honor of Poseidon. The festival was also known as the *Isthmia*. The athletic competitions usually were held in the spring of the first year and the summer of the third year of each Olympiad, the four-year interval between the Olympic festivals. The contests included foot races, strength and endurance tests, four-horse chariot races, horse racing, wrestling, boxing, and quoit and javelin throwing. Victors were adorned with crowns of celery or parsley.

In Greek legend, the origin of the Isthmian Games is ascribed variously to Poseidon, Theseus, and Sisyphus. By 581 B.C. the games had taken definite shape as a Panhellenic festival.

ISTHMUS, is'məs, is a narrow strip of land running through a body of water and connecting two larger land areas. The word is of Greek origin, possibly deriving from *ithma* (step), and was first applied to the land passage between the Peloponnesus and the Greek mainland, known as the Isthmus of Corinth.

Other famous isthmuses are the Isthmus of Suez, joining Asia and Africa; the Isthmus of Panama, connecting North and South America; and the Isthmus of Perekop in the Soviet Union, joining the Ukraine with Crimea. The isthmuses of Panama and Suez are crossed by the world's two most famous sea-to-sea canals, the Panama and the Suez.

ISTLE, ist'lē, is a hard vegetable fiber obtained from several species of plants of the genera *Agave* and *Bromelia*, especially *A. lophantha* var. *poselgaea* and *B. sylvestris*. The fiber is also called *ixtle*, *tula*, or *tampico*, the latter for the port of Tampico, Mexico, which ships large quantities of it. Istle is used for cordage, sacks, belts, hammocks, and mats. It comes from the *cogollo*, or central spike, of unopened leaves of the agave or bromelia. The leaves are separated by hand and scraped on both sides with a dull-edged knife so as to release the fiber lying immediately under the epidermis. Istle-yielding plants grow wild in the southwestern United States, Mexico, Central America, and parts of South America. They are cultivated for their fiber chiefly in the Mexican states of Coahuila, Nuevo León, San Luis Potosí, and Tamaulipas.

ISTRIA, is'trē-ə, is a peninsula in northwestern Yugoslavia, in the Croatian republic. It extends about 60 miles south from the Karst plateau into the Adriatic Sea, between the gulfs of Trieste (on the west) and Veliki Kvarner (on the east). The area of the peninsula is about 1,545 square miles, and the coastline extends some 265 miles.

Istria is chiefly an agricultural area, populated by Slavic and Italian peasants. Important products include cereals, fruits, lumber, and cattle. Olives, olive oil, and wines figure prominently in its export trade. Extractive products include alum, bauxite, coal, marble, mercury, and salt. There is also considerable fishing along the Istrian coast, and summer resorts abound. The most important city is Pula (1961 population, 37,403), a port, naval base, and industrial and shipbuilding center on the west coast near the southern tip of the peninsula. North of Pula are the port towns of Poreč and Rovinj. The large port of Rijeka (1961 population, 100,989) lies just east of Istria's northeast border.

History. Istria was already inhabited when the Romans conquered it in 177 B.C. It remained nominally under Byzantine rule after the fall of the Western Roman empire, but was overrun by Lombards and Goths. In 788–789 A.D., it was annexed by the Franks as the Carolingian march of Istria. Subsequent overlords included the dukes of Carinthia and the patriarchs of Aquileia. In the 900's, Istria was united to the duchy of Bavaria.

By the 1400's, Austria and Venice had absorbed the northeastern and southwestern portions respectively. The Treaty of Campo Formio (1797) and decisions of the Congress of Vienna (1815) gave the Venetian portion to Austria. In 1915, according to the Treaty of London, Italy was promised Istria and other Austrian territory as a reward for her entrance into World War I on the side of the Allies. By the Treaty of Rapallo (1920), this promise was fulfilled. The bulk of Istria was transferred to the Italian department of Venezia Giulia e Zara.

In the summer of 1945, following the collapse of Germany in World War II, the peninsula was occupied by Yugoslav forces. The Treaty of Paris (1947) gave most of the peninsula to Yugoslavia, while the northwestern sector became the Free Territory of Trieste. By an international agreement in 1954, the city of Trieste and a small area of adjoining land was returned to Italy. The greater portion of the former free territory went to Yugoslavia.

ISVOLSKY, is'vôl-skē, **Aleksandr Petrovitch**, Russian diplomat: b. Moscow, Russia, March 18, 1856; d. Paris, France, Aug. 18, 1919. At the age of 22, Isvolsky was sent on a mission to Pope Leo XIII, which resulted in the reestablishment of Russian relations with the Vatican and his own appointment as Russian chargé d'affaires. He was successively minister to Serbia (1897–1900) and to Japan (1900–1902). In Tokyo he tried to overcome the resentment felt in Japan against Russia, which had compelled Japan to yield territory on the mainland of Asia which it had won in war against China (1894–95). He was unsuccessful, and in 1904 Japan and Russia were at war.

Isvolsky became foreign minister of Russia in 1906. The next year he negotiated an agreement with Great Britain that eased some frictions between the powers. In the diplomatic crisis that followed Austrian annexation of Bosnia and Herzegovina in 1908, he tried to secure from Turkey the right for Russian warships to pass from the Black Sea through the Dardanelles and the Bosphorus to the Mediterranean Sea. But the failure of this effort weakened his position at home, and he retired from the foreign office in 1910. He served as ambassador to France from 1910 to 1917.

ITAGAKI, ē-tā-gā-kē, **Taisuke**, Japanese political leader: b. Tosa province (now Kochi prefecture), Shikoku, Japan, April 17, 1837; d. Gifu, Aug. 16, 1919. He founded the first political party in Japan and was a steadfast fighter for political freedom and liberal constitutional government. When an attempt was made on his life in 1882, he is said to have remarked: "Itagaki may die, but liberty will live."

Itagaki received a military education and commanded troops of the Tosa clan in the service of the emperor during the struggle that overthrew the shogunate and restored the Meiji regime in 1868. From 1871 to 1873 he was councillor of state to the emperor. He then resigned to become the center of a movement for constitutional government. Itagaki favored a constitutional system like Britain's rather than the strong monarchy, like Germany's, that was finally adopted in 1889. However, as a fervent nationalist, he was willing to sacrifice some popular rights for strong government.

Early in 1878 he established a private school in Tosa devoted to teaching the principles of democratic government. This school gained great popularity, and Itagaki became known as the "Rousseau of Japan." Japan was then thought to be on the point of revolution, and the government, feeling the pressure of public demand, invited Itagaki into the cabinet. He accepted appointments as minister of public works in 1878 and minister of the interior in 1880.

In 1881 he organized the *Jiyuto*, or Liberals, the first Japanese political party. In the 1890's, with the goal of parliamentary government accomplished, he lost interest in politics. However, he continued to hold cabinet posts until he retired in 1900. He was made a count in 1887.

ITALIAN EAST AFRICA, Italy's former possessions in East Africa. See ETHIOPIA; SOMALIA, REPUBLIC OF.

ITALIAN SOMALILAND. See SOMALIA, REPUBLIC OF.

ITALY, it'ā-lē, is a republic of western Europe. It is a key member of the North Atlantic Treaty Organization and the European Economic Community. An illustrious land with a civilization dating back several thousand years, Italy has enriched the world since the days of ancient Rome with its brilliant achievements in the arts, sciences, religion, government, and law.

Modern Italy was not united until 1861. It was ruled by the house of Savoy from 1861 to 1946, when the Italians voted to replace the monarchy with a republic.

Italy's area of 116,303 square miles is divided into 20 regions. Rome is the capital. The estimated population of Italy in 1965 was 52,520,000 (1961 census: 50,623,569).

The Italian name for the country is *Italia*. Its national flag is a tricolor of green, white, and red vertical stripes. The national anthem is the *Inno di Mameli* (*Hymn of Mameli*), a famous anthem of the Risorgimento—the movement for the liberation and unification of Italy in the 1800's. The basic monetary unit is the lira (622.38 lire equaled US\$1 in 1965). The metric system is used for all weights and measures.

1. THE LAND. Geographical Position.—

Italy lies in the same latitudes as the eastern United States from northern Maine to southern Virginia. Mainland Italy is the middle peninsula of the three that form the southern extension of Europe. The Mediterranean Sea forms three basins around the peninsula—the Tyrrhenian Sea on the west, the Ionian Sea on the south, and the Adriatic Sea on the east. Italy is bounded on the north by the great mountain chain of the Alps. South of the peninsula, and separated from it by the narrow Strait of Messina, is the Italian island of Sicily. Italy also includes the island of Sardinia, west of the peninsula, some small islands off the coast of Africa in the Mediterranean Sea, and minor groups of islands in the Tyrrhenian Sea. The island of Corsica, just north of Sardinia, falls within the geographic zone of Italy but belongs to France.

With the exception of the boundary with Yugoslavia, the present limits of Italy were fixed in the peace treaty signed between the Allied and Associated Powers and Italy on Feb. 10, 1947. In general, the French-Italian border is marked by the watershed of the western Alps. The watershed of the central Alps forms the frontier with Switzerland and Austria, except that the upper basin of the Ticino River and a small part of the upper basin of the Adige River belong to Switzerland. Before World War II, the natural line of the Julian Alps was the boundary with Yugoslavia. By the peace treaty of 1947, Italy ceded to Yugoslavia most of the Istrian peninsula and the upper basin of the Isonzo River. The port of Trieste, however, with a small surrounding territory (277 square miles in all), was made a free territory.

The free territory was the subject of continuous dispute between Italy and Yugoslavia. It

was finally partitioned between them in 1954. The city of Trieste and most of the northern part of the territory was transferred to Italy; the remainder went to Yugoslavia.

Two independent states are entirely surrounded by Italy: the republic of San Marino (23 square miles, near the northern Adriatic coast), and Vatican City (109 acres in Rome), the temporal dominion of the pope.

The Setting.—The Italian peninsula extends into the Mediterranean like a huge boot more than 720 miles long and 80 to 150 miles wide. The distance across the Strait of Otranto, between the southeastern end of the peninsula and the Balkan Peninsula, is only 44 miles; the distance between Sicily and Africa is 90 miles. The Sicilian city of Messina is about midway between Gibraltar and the Suez Canal. Because of this central location, Italy has always played a prominent role in the Mediterranean.

Seacoast.—The length of the Italian coastline is about 4,971 miles, of which 2,237 belong to the mainland and 2,734 to the larger and smaller islands.

The northwestern coast on the Ligurian Sea is high and steep because the mountains are close to the water. The coast bends to form the wide Gulf of Genoa. The port of Genoa is the outlet of the most important industrial districts of Italy. The Gulf of La Spezia, at the eastern end of the Riviera, is less wide.

On the western side of the peninsula, the coast of the Tyrrhenian Sea forms a series of sickle-shaped gulfs separated by high promontories. The wide splendid Bay of Naples, surrounded by an exceptionally fertile plain, attracts the greatest part of the maritime activity of southern Italy.

The Ionian seacoast, on the south, is generally straight and lacking in good harbors. The chief port is Taranto, on the Gulf of Taranto.

The Adriatic coast on the east is also generally poor in harbors. Brindisi and Bari acquired some importance in the 20th century because of trade with the Middle East. Ancona, sheltered by Monte Conero, is one center of maritime trade between Italy and the Balkan Peninsula. In the extreme north, where the coast is low with many lagoons and marshy tracts, is the port of Venice.

In Sicily, the best ports are on the northern coast (Palermo) and the eastern coast (Catania and Syracuse). The Sardinian coast has few good harbors except in the south (Gulf of Cagliari).

Geomorphology.—Italy is divided into four geomorphic regions: (1) the internal or southern slopes of the Alps; (2) the plains of the Po and Venetia; (3) the peninsula, with Sicily; and (4) Sardinia.

The Alps.—The Alps belong to the family of young Mediterranean chains (Alpids) in which folding continued during all of the Tertiary period. They are a series of big and often very irregular corrugations separated from each other by longitudinal valleys, which form deep furrows. The highest tracts of the ridges are ordinarily found in the middle portion, where crystalline rocks (granite, gneiss, schists) predominate. In the western portion (Italo-French Alps) this higher ridge slopes precipitously toward the plain of the Po; but in the central portion (east of Lake Como) and in the eastern portion the higher ridge is bordered by chains of a lesser

altitude made up of sedimentary rocks with limestone predominating. These are the Outer Alps (Prealpi).

Along the French border are the chains of the Maritime, Cottian, and Graian Alps. Then, proceeding east along the Swiss and Austrian borders are the Pennine, Lepontine, and Rhaetian Alps, and then the Dolomites. To the east are the Carnic and Julian Alps, the latter largely Yugoslav. The highest peak is Mont Blanc (Monte Bianco), in France, which reaches 15,781 feet. All of the peaks over 13,000 feet are in the central Alps with the exception of the French Mont Pelvoux and the Italian Gran Paradiso, in the Graians, which is 13,323 feet high. In the Pennines are Monte Rosa (15,217 feet); the Matterhorn (Mont Cervin; Monte Cervino), Swiss and Italian, which is 14,780 feet high; and Dent d'Herens (Swiss and Italian, 13,690 feet). Monte Viso, in the Cottian Alps, is 12,601 feet high. The highest peak in the Dolomites is Marmolada (10,964 feet). These higher mountains, as well as many others attaining more than 10,000 feet, are covered with large glaciers, the limits of permanent snow being between 8,200 and 9,200 feet.

The Alps are indented by deep transverse valleys, situated in a normal or oblique direction to the geographical axis of the chains. These valleys (such as the Adige) reach the heart of the mountainous region and lead to passes which facilitate the crossing of the system. The passes become gradually lower from west to east; that is why the eastern portion of the Alps is generally easier to cross than the western part.

The Plain of the Po.—At the foot of the Alps extends the largest Italian plain, formed by the hydrographic basin of the Po and of the Venetian rivers (Adige, Piave, Tagliamento). This plain covers about 17 per cent of Italy's total area, and from an agricultural and industrial standpoint, it is the most important region of Italy. The more elevated portion is devoted to grain and mulberry trees. In some of the drier parts agriculture must be assisted by irrigation. In the lower portion, in contrast, there are still some wet and marshy parts which require drainage. This portion is devoted to the two main agricultural products of Italy, rice and fodder grass. Cultivation of the latter results in a flourishing butter and cheese industry. Along the Adriatic coast there was in antiquity a succession of lagoons, but many of them were reclaimed beginning in the 16th century.

The Apennines.—The Apennines form, orographically but not geologically, the continuation of the Maritime Alps along the Gulf of Genoa, and they stretch down the whole peninsula to the Strait of Messina. The name Apennines applies, however, only to the middle chains, which, in the northern portion (Tuscan and Umbrian Apennines), are situated in succession from west to east like the wings on a stage, gradually approaching the Adriatic Sea. In the central and highest portion, within the limits of Abruzzo, the Apennines form two or three main ridges enclosing highlands and elevated basins. In the southern portion (Campania and Calabria) they divide into clusters and groups separated by low areas. The geological formation and external aspects of the Apennines are varied in the different portions. On the whole, however, the scenery of the Apennines is not so impressive and picturesque as the Alpine scenery, because of the

lower altitude, the lack of glaciers, and the smaller amount of water—the last due mainly to the fact that the mountains have been gradually deprived of their vegetation. The highest group of the Apennines is the Gran Sasso (Monte Corno, 9,560 feet). Other groups which attain a considerable altitude are the Sibillini (Monte Vettore, 8,127 feet), Monti della Laga (Monte Gorzano, 8,055 feet), the Terminillo (7,261 feet), the Maiella (9,170 feet), the Velino (8,160 feet), and the Mèta (7,372 feet).

The passes from the Tyrrhenian toward the Adriatic slope are numerous but, especially in the central portion, they are at a great altitude and are therefore obstructed by snow in winter.

Some isolated elevations on the Tyrrhenian side form the so-called Antiapennines, of volcanic formation. On the peninsular portion of Italy only one active volcano is found, namely, Vesuvius (Vesuvio, 3,858 feet), but several other volcanoes, still active in the Quaternary period, have retained their characteristic aspect. Such are the Amiata, in southern Tuscany (5,689 feet), the groups of the Vulsini, Cimini, Sabatini, and Albani, in Latium; the volcano of Roccamonfina (3,291 feet), in Campania; the Campi Flegrei where, as recently as 1538, a volcanic eruption resulted in a new mountain called Monte Nuovo; the Epomeo (San Nicola, 2,589 feet), in the island of Ischia, still active in the 14th century; and Monte Vulture (4,357 feet), Basilicata. On the Adriatic side, isolated elevations are Monte Gargano, the spur of the boot of Italy (3,465 feet), and the plateau of the Murge, which has very little water.

The plains of the peninsula are few and small. Along the Tyrrhenian Sea, the Maremma and the Pontine marshes have been both reclaimed in the 20th century. Farther south is the very fertile plain of Campania. Along the Adriatic Sea the Tavoliere of Apulia and the plains of Salento are found. In the inland portion some small plains amid the mountains were occupied by lakes in quite recent geological times. One of these lakes, Fucino, was drained only in the 19th century by means of an artificial effluent.

The mountains of northern Sicily are considered a continuation of the Apennines beyond the Strait of Messina. The highest group, called Le Madonie, is only 6,780 feet high. But Sicily has a thoroughly isolated and active volcano, Mount Etna (10,758 feet). South of this mountain extends the largest plain of the island, the Piana di Catania.

Sardinia.—Sardinia, with the French island of Corsica, forms a distinct portion, because it is probably the remains of a more ancient land (Tyrrhenys) which occupied a part of the Tyrrhenian Sea prior to the formation of the Italian peninsula. Ancient geological formations are therefore prevalent in Sardinia, where they form the framework of isolated mountain groups, the highest of which is Monti del Gennargentu (6,017 feet). Other fragments of ancient Tyrrhenys are the island of Elba and the elevations of southern Tuscany. Sardinia, Elba, and southern Tuscany are also the only really important regions from the viewpoint of mineral products. Useful minerals are scarce in Italy, where fossil fuels in the proper sense are lacking. In Sicily much sulphur is found; the Apuan Alps yield the well-known Carrara marble; the western Alps, a little iron; and the Trentine Alps, some metallic minerals.

Climate.—The complexity of the physical structure of Italy is increased by the remarkable climatic differences in the various regions, so that it is impossible to speak accurately of a "climate of Italy." The latitude range of $10^{\circ}29'$ between the extreme north and south would be sufficient in itself to cause considerable differences in temperature. But, in addition, the peninsula stretches far into the Mediterranean Sea, where seasonal alternations are felt only by a superficial layer of 1,000 feet, while all the remaining water down to the bottom has an almost constant temperature of 55°F . In winter, the Mediterranean is therefore a reservoir of warmth; in summer it is relatively cool. The influence of the Mediterranean thus accounts for mild winters and moderately hot summers. The farther a region is from the sea, the less this influence is felt, and in continental Italy the influence of the Mediterranean is almost negligible. However, the mountainous bulwark of the Alps protects this area against cold north winds and, in general, against the atmospheric influences of the north. The Alpine shelter is remarkably reduced in the eastern portion (the Venetian region and Istria), and here the northern influences are often felt in the severely cold and violent winds called *bora*. A climatic influence is also exerted by the Apennines. Because of this mountain system, the influence of the western winds from the Atlantic is limited to the Tyrrhenian side of the peninsula, and in the northern portion the favorable influence of the Tyrrhenian Sea is limited to the narrow southern slopes of the Ligurian Riviera.

With regard to temperature, Italy is broadly included between the annual isotherms of 52° and 66°F .; the coldest period occurs in December and January, the hottest in July and August. In the plain of the Po the average annual temperature is about 55°F .; in Sicily it is about 64° —a difference of 9° in relation to a distance of about 500 miles. The difference would certainly be greater but for the Alpine bulwark and the tempering action of the Mediterranean Sea. In continental Italy, the differences of temperature between summer and winter are very remarkable; in the central portion of the plain of the Po, differences of 36° – 43°F . between average July and January temperatures are observed; in the inland portion of the peninsula also, in the mountainous regions of the Apennines—for instance, at L'Aquila—such differences exceed 36°F .

Even more remarkable are the differences in rainfall. In the Alpine region the rain is more and more copious as the altitude rises; in the eastern Alps and Outer Alps, as well as in the mountains between Lago Maggiore and Lago di Como, the annual precipitation exceeds 80 inches. The same amount is found also in some of the higher portions of the Apennines exposed to the western winds. The driest portions are the low areas far from mountainous elevations. In the eastern plain of the Po, a small area receives less than 24 inches, and rainfall is no greater in the Tuscan Maremma and the plains of Latium. (The general average in the north, however, is about 50 inches.) The Tavoliere of Apulia, the southeastern portion of Sicily, and the southern plains of Sardinia receive less than 20 inches.

No less important than the annual rainfall is the manner in which it is distributed in the various seasons. In the whole area of Italy south of the Tiber (Tevere) and Tronto rivers,

including the larger islands, rain falls mostly in winter, and the summers are very dry. This phenomenon is typical of the Mediterranean climate. In Apulia, Sicily, and Sardinia there are three months with practically no rain at all. Such a long drought is likely to damage crops and pasture, and the need of water for agricultural purposes is keenly felt. In the center of the Alps, on the other hand, rainfall shows a tendency to concentrate in summer. During the winter there is a copious fall of snow which covers the ground for a long period. The same conditions are shared by the plain of the Po. The freezing of rivers, however, is almost unknown; even in the Venetian lagoon, freezing rarely occurs.

In some regions the climate is often modified by local conditions. Such is the case of the waters of the large subalpine lakes which exert a mitigating influence not unlike that of the Mediterranean. This is why, on Lago Maggiore and on Lago di Como and Lago di Garda, there are resorts with a Mediterranean climate. Again, in the center of the Alps, some well-sheltered valleys and some dells (such as the Merano dell) have a mild and dry climate. The mild climate of the Ligurian Riviera is celebrated; this region is encircled by the Apennines and opened southward to the favorable influence of the Tyrrhenian Sea.

Rivers.—The characteristics of the Italian rivers are determined by morphological and climatic conditions. The largest of them originated in the area bounded by the Alps and the Apennines, which was covered by the sea until the Quaternary period. The Po is the only river which crosses the whole plain from west to east; its course is about 420 miles long, with a drainage basin of some 29,000 square miles. The river is subject to two periods of high water. The principal one takes place around June; the lesser one in October. The low-water periods occur in January and August. Some of its Alpine tributaries, such as the Ticino, Adda, Oglio, and Mincio, have an ample, clear, and regular flow because they are fed by the Alpine glaciers and by many springs, and because they cross the large subalpine lakes, which act as regulators and clear their waters. On the other hand, the Apennine tributaries of the Po, such as the Tanaro, Trebbia, Taro, Secchia, and Panaro, are impetuous in the mountainous portion of their courses, irregular, and full of sediment. This is carried by the Po into the Adriatic, where the delta of the river, though subject to various alterations, is steadily increasing. It did not exist in the time of ancient Rome and was built up in the last 20 centuries. The importance of the different mouths has varied from time to time; the greatest volume of water is carried at present by the Po della Pila. The Po is subject to violent and disastrous floods; therefore, the entire lower course of the river, downstream from Cremona, has been securely dammed. As a waterway, the river has had little importance. Great works are in progress, however, with a view to opening a waterway from the Adriatic to Milan and Lago Maggiore.

The large northern plain is also crossed by the Adige and by some others of the longest Italian rivers, such as the Piave, the Tagliamento, and the Isonzo. In length, the Adige is third among the Italian rivers (220 miles). Its upper course is mountainous and often narrow and en-

ITALY is divided for administrative purposes into 19 regions, shown on the map in separate colors. The regions of Friuli-Venezia Giulia, Sardinia, Sicily, Trentino-Alto Adige and Valle d'Aosta enjoy special autonomy.

The regions are subdivided into provinces bearing the same names as their respective capitals, except:

closed. After the gorge called Chiusa di Verona, famous in military history, the river enters the plain. In its lower course, the Adige has often shifted its bed; it is subject to violent floods and is navigable only by small craft.

The rivers of the peninsula portion of Italy are characterized by a considerable slope, especially in their upper courses, and by irregularity, with floods in spring and low water in summer. The rivers which empty in the Adriatic and Ionian seas flow in short transverse valleys; the longest of them are the Tronto, Pescara, and Ofanto. On the Tyrrhenian side more important rivers are found. The Tiber, which is a little longer than the Adige (244 miles), carries the waters of the principal mountainous groups of the central Apennines and has some notable tributaries, among them the Nera and the Aniene. Its lower course crosses the Roman Campagna. On its delta there was in antiquity the port of Rome, called Ostia, now filled with earth because of a very conspicuous alluvial process. Other notable rivers on the Tyrrhenian side are the Tuscan river Arno, north of the Tiber, and the Liri and Volturno south of the Tiber.

In Calabria and northeastern Sicily there are characteristic torrents, called *fiumare*, which are quite waterless during many months of the year and muddy and impetuous in the rainy season.

The Italian rivers are of little importance for navigation. However, the rivers of Alpine Italy are profitably used for irrigation, and above all for the production of electric power. For the same purpose, important plants have also been established on some rivers of the peninsula, such as the Aniene and the Nera, and on some rivers of Calabria, Sicily, and Sardinia.

Lakes.—The Italian lakes are divided into two main groups. The first includes the large subalpine lakes—Lago Maggiore or Verbano, Lago di Como or Lario, Lago d'Isèo or Sebino, and Lago di Garda or Benaco. They were all formed by ancient valleys once occupied by the extensive glaciers of the ice age, and are barred at the lower end by the terminal moraines of these glaciers. Their shores, favored with a mild climate, are thickly settled. The second group is in the Antiapennines and consists mostly of lakes which occupy the craters of ancient volcanoes. Such are the lakes of Bolsena, Vico, Bracciano, Albano, and Nemi. In contrast, Lago Trasimeno occupies a low area which is the remainder of a larger but very shallow basin. Other lakes, such as Fucino, have been drained.

Several small lakes are scattered along the coast of Latium, Campania, Apulia, and Sardinia; some have been reclaimed in the 20th century. There are also numerous artificial lakes or reservoirs for the production of electric power; some of the largest of these are found in the Venetian Alps, in Calabria, and Sardinia.

Plant and Animal Life.—In a country with such an ancient civilization as Italy has the natural landscape, as affected by the conditions of climate and soil, has been deeply modified by man. Mountain flora, with relics of the ice age, is found in the Alps above 6,500 feet, and in the Apennines above 7,200 to 7,900 feet. The belt of highest woods was originally, and is still partly, formed by conifers, but it was severely damaged by deforestation, which began in the Roman period and has been very actively pursued ever since with the exception of some pauses during the early Middle Ages. Below this altitude is a

belt of such plants as beeches (still found in some regions of the eastern Alps and Outer Alps and of the Apennines), oaks, and chestnut trees. Oak woods, very widespread in antiquity, have suffered the heaviest damages from deforestation, particularly in the central and southern Apennines and in Sicily. Extensive oak woods still remain in Sardinia, however.

The plain of the Po has also thoroughly changed its original aspect. In the higher portion, which is very dry, there were once extensive areas with a scanty vegetation. These were later taken over for tillage by means of irrigation. Some small pieces of untilled territory, known variously as *brughiere*, *groane*, and *magredi*, still remain in Piedmont, Lombardy, and the Venetian region. In its lower portion, the plain was formerly covered with many marshy areas subject to floods, where poplars and willows thrived. But today the plain is almost entirely tilled, largely with cereal grains, rice, and hemp, or given over to pasture.

In the peninsula and in the larger islands, the hilly and level areas as well as the larger inland valleys were and still are the domain of Mediterranean vegetation. A natural formation was the *macchia*, or bush, with evergreen trees and such shrubs as holm oak, cork trees, juniper, bramble, mastic, broom, laurel, myrtle, and dwarf palm. Since remote times man has eradicated this natural vegetation in extensive areas and replaced it with other growths, chiefly the olive tree, an appropriate emblem of the Mediterranean regions. Other cultivated plants are vines, and some fruit trees such as figs and almonds. Lemon and orange trees were imported in more recent times. Wheat thrives almost everywhere, but in the south and in Sicily it is often damaged because of the irregularity of rainfall. Among recent growths are sugar beets and tobacco. A typical feature of the Mediterranean landscape was the maritime or Italian cluster pine in the coastal areas, but there are few such pine groves left.
